INDEX TO VOLUME II FOR 1945

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate headings—for example, Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma; Child and Infant; Goitre and Thyroid. Subjects dealt with under various main headings in the JOURNAL have been set out in alphabetical order under their respective headings—for example, "Annotations," "Correspondence," "Leading Articles," "Obituary," "Reviews," etc. Original Articles are indicated by the letter (O).

A

Adenoma, visceral lesions of, after muscular action, 158
 AL, Lawrence: "Siren diarrhoea," 52
 ALSON, B. R.: In defence of nursery schools, 72, 72S
 ALHAM, J. Johnston: Appreciation of Charles Gibbs, 529
 ALKUMSON, Mervyn: Whole-time security, 182
 case, amoebic liver, an unusual case of (J. A. M. Lamont), 529
 ANGLY, ROYAL OF MEDICINE IN IRELAND:
 Reports of 1-42-3 Session, 656
Journal of Anatomy and Physiology: Ascorbic acid in idiopathic methaemoglobinemia, 335
 Ascorbic acid, planning of (annotation), 112
 Ascorbic acid in a man of 60, 532
 Ascorbic acid, 75 cases of: effect of removal of tonsils and adenoids (H. J. G. Garceau), 57
 Ascorbic acid of tongue successfully treated by diphenamides (A. McCloy), 106; correspondence, 180
 ASH, A. Wilford: Conditions for good work, 52, 11
 — F. Dennett: *Physical Diets* (Richard C. Brock's original work) 13th ed., 75
 Ashtabula, 54
 Ashtabula, arterial hypertension, 31
 Ashtabula: Severe action of vitamin C on the adrenals, 213—Clinical symptoms of adrenocortical hyp- and hypotrophy, 825
 Ashtabula, space, economy in, 57, annotation on, 18; correspondence, 730
 Ashtabula, Centre: Treatment of leprosy, 531
 Ashtabula, soldiers, analysis of acute respiratory conditions in (W. W. MacNaught and R. M. Murray), 324 (O)
 Ashtabula, *Care and Rehabilitation: A "Practitioner" book* 265
 Ashtabula, 690
 Ashtabula, H.: Peripheral arterial embolism, 101 (O); correspondence, 179, 245, 374
 Ashtabula, *Procedures*: Police decoy and the doctor (notation), 719; correspondence, 725, 796, 832
 — Question in Parliament, 733
 ASH-FERRANT, T.: Polymyositis in Malta, 687
 ASH-FERRANT, C. B.: Arsenical encephalopathy, 465
 planning the (annotation), 459; correspondence, 180, 604
 Ashtabula, casualties, colour film of, 840
 Ashtabula, John, obituary notice of, 346
 Ashtabula, Robert: Treatment of lupus vulgaris, 463, 621
 Ashtabula, Helen Bower: Advantages to nitrous oxide anaesthesia, 762
 Ashtabula, John: And the brain (annotation), 112—And nitaminism (annotation), 614; correspondence, 18
 Ashtabula, infection, Gasserian trigeminal neuralgia at an exceptionally early age cured by (Wilfred Harris), 100
 RIDGE, L. W.: Specialist courses for Service (O.S.), 58
 ASH-FERRANT, G. L.: Psychiatry in general hospitals, 14
 Ashtabula, 802
 Ashtabula, Liver, sensitivity to, 29—Bees-stung, 62—Ashtabula, 140—Hay-fever and allergic rhinitis, 4
 ASH-FERRANT, P. R.: Management of acute renal pneumonia, 353 (O); correspondence, 463, 591
 — R. S.: *Sea Diseases: The Story of a Great Naval Experiment in Preventive Medicine* (in the Royal Navy), 338
 ASH-FERRANT, E. N.: Excretion of sulphamides in the sea, 380
 ASH-FERRANT, A. Cecil: Appreciation of A. W. Burre, 6
 Ashtabula: Home service, 172—Availability of, rough Red Cross, 254
 Ashtabula, primary, 834
 Ashtabula, nes, pressor, and arterial hypertension, 32
 Ashtabula, methamine in narcolepsy, 533
 Ashtabula, two-stage: Primary planned amputation in presence of sepsis (E. A. Jack and J. Hamley), 131 (O)

Amlyoid disease, primary (J. A. Dillon and L. R. Evans), 242
 ANAEMIA
 Anaemic (annotation), 237
 Hypochromic, in adolescent males (M. L. Thomson), 454 (O)
 Liver deficiency, in a case of acute infective hepatitis (J. Norman Hill and Walter Hausmann), 262 (O)
 Nutritional iron deficiency in war-time haemoglobin levels of 333 persons from birth to 55 years of age (L. S. P. David and J. Harris), 36 (O)
 Pernicious, and having children, 4-3
 — of pregnancy, 464
 Therapeutic failures (notation), 574
 Anaerobiosis, pathogenic (F. A. G. O.), 52
 ANAESTHESIA
 Anaesthetics, teaching, 527
 Anaesthetics, third hand (P. S. A. Hay), 484; correspondence, 725, 765
 Caudal, continuous in obstetric anaesthesia, 508
 Ether, light, 762
 For laryngoscopy, 312
 Gas-and-oxygen equipment for, 495
 Intravenous, continuous, simple (R. Shaw), 714
 (F. W. Roberts and B. A. Sulick), 713 (O)
 Nasal intubation, 85
 Nitrous oxide, a critical evaluation (R. Shaw Gould), 607 (O); correspondence, 762, 827
 Obstetric, Guthrie's, 700
 Reversal, 660
 Spinal, concentration of narcotic for, 457
 — low during labour in cases of cardiac failure (H. Burton), 359 (O); correspondence, 458
 — use of carbolic after, 179
 — specific gravity of C.S.F. with special reference to (W. Etherington Wilson), 165 (O); correspondence, 245, 250, 514
 Trichloroethylene and muscular paralysis (J. McAuley), 713; correspondence, 828
 Anaesthesia, gas-and-air, apparatus supplied to maternity homes, 696—In midwifery, a "mechanical midwife," 795
 Anaphylactic shock after first injection of tetanus serum (K. Bradd), 11
 Anatomy: Of morals (book review), 41—Teachings of (Nova et Vetera), 49—Vesal, 4 and Gray on 56—Surgical, aids to (book review), 76—Comparative topographical (book review), 10
 Regional (book review), 202—Nomenclature, 345
 —Of female pelvis (book review), 514—A Guide to (E. D. Ewart), 5th ed., 647—Cunningham's *Textbook of*, 8th ed., 782
 Anderson, Hannah Perry, obituary notice of, 530, 593
 — H. S.: Fleas and cockroaches, 840
 — Sir John: Medicine, 52
 — Louisa Garrett, obituary notice of, 695
 — Manuel: Faecal and labial dysphagia, 104 (O)
 — Robert: The common cold, 559
 — Thomas: Effect of chemotherapy on mortality from pneumonia in Glasgow, 77 (O)
 — W. A. D.: *Synopsis of Pathology*, 300
 ANDREWS, C. H.: Typhus fever (OX 19, NK, and undetermined), 521
 ANDREWS, Mr.: Photographing patients in bed, 521
 — Albert H.: *Manual of Ocular Therapy*, 1st ed., 1944, including *Carboxy Dye Hydrolysis and Water Vapor*, 76
 Aneurism, revised procedure for estimation of, in urine by thiochrome test: Assessment of level of nutrition (Y. L. Wang and L. J. Harris), 451 (O)
 Aneurysm, arteriosclerotic, of abdominal aorta with perforation of upper jejunum (W. Hausmann), 362
 — arteriovenous, of neck (M. H. Waters), 106
 — survival after wiring, 442
 Areflexia, paretic, 573
 Ariline intoxication (annotation), 457
 ARNOLD, W. Fraser: Treatment with tuberculin 19

Annotations:

Abortion, among women workers, 338
 Accident services, planning of, 112
 Air, above, planning the, 459
 Alcohol and avitaminosis, 614
 — and the brain, 112
 Anaemia, clinical, 237
 Anaesthesia, in obstetrics, 262
 Aniline intoxication, 457
 Anopheles gambiae, eradication of, in Brazil, 520
 Association, British Medical: Death of President, 175—Lord Dawson, our President (J. M. Charnley), 443
 — membership of Council, 443
 — Hospital, 149
 Beryllium toxic effects of, 450
 Bill of health, 175—great cases, 752
 Borna disease, clinical, 271
 Bath weights, manipulation of, 427
 Blood irradiation therapy, 615
 Cerebral malnutrition, 144
 Chest surgery film, 397
 Children in bordereaux, 238
 — in hospital, 785
 — school, medical care of, 304
 Coarctation, 535
 College, Royal of Surgeons, New Royal, 117
 Fellowship, 82—Endowment of Chair of Human and Comparative Pathology, 518
 Colonial research, 420
 Council, Medical Research, 719
 Dawson, Lord our President, 425
 Demerol, 369
 Deuterium and salivates, 615
 Digitalis, action of, 45
 Dilator for non-patients, psychoses, 517
 ECG diagnosis, a point in, 83
 Electroencephalogram, psychopathic personality, 718
 — and, 718
 Emetics, infantile and breast-feeding in, 140
 Eskimo and Lapland, food and health of, 207
 Europe, food situation in, 16
 Evaluation, a broader picture, 46
 Ever-injured by mustard gas, treatment of, 111
 Evans, G. W.: midwife in 17
 — doctors in, 51
 Friends in need, 744
 Goitre in County Tipperary, 79
 Gonorrhoea, chronic and acute, 120
 Haematocrit, herbal, 236
 Haemoglobin, malaria, 19
 Hormones, plant, 175
 Hospital diets, inadequate, 521
 Hospitals, voluntary, look forward, 302
 Hypertension and health, 365
 — experimental treatment of, 614
 Hypocriticism and patient behaviour, 366
 Insects, half-yearly, 652
 Industrial health in 1942, 559
 Infants' reaction to food, 821
 Influenza, nature of virus, 175
 Journal, British Medical, appeal for book numbers, 256, 45
 — of Industrial Medicine, 554
 Kala-azar, transmission by sandfly, 45
 Kidneys: Phosphate renal calculus, 551
 Lenses, contact for flying duties, 18
 Liver pills, efficacy of, 353
 Lupus vulgaris, treatment of, 356
 Medical: General, a substantial work in
 — Benial, 425—Control in Freeport Harbour, 719
 Males, med. and specialists for, 719
 Measles vaccine, 304
 Medical history of the war, 652
 Medicine in Persia, 820
 Mental health care, views on, 72
 Midwives, shortage of, 333
 Milk: Cleaning bottles, 272
 Ministerial chaos, 650
 Morbidity, familial, and microphemia, 417
 Narcotics, control of, 18
 Oestrogens and endocrine system, 753
 Nervous shock, 110
 Nurses, hospital, health of, 428
 Ophthalmology: Teaching of, 144—Review, 144
 — and, 718
 Organisms of medical profession, 552
 Palsy, facial, medical of, 752

Annotations (continued):

- Pancreatic islets, factors damaging, 17
Paper control and the war of ideas, 518
Parathyroid action, site of, 176
Parent in the dock, 551
Patulin and the common cold, 683
Pellagra, rastric factor in, 18
Penicillin in Tunisia, 650
Poisoning: From hair dye, 490—Tricresyl phosphate, 682—Arsine, 785
Police decoy and the doctor, 719
Polionmyelitis, 459
Proctitis, factitial, 459
Rat, brown, war on the, 786
Respiratory function of digestive tract, 207
Rheumatic fever, 516
Ross Institute of Tropical Hygiene, 17
Shigella, the genus, 237
"Shock" from venous occlusion, 143
Society, Clinical, of London, 651
— Research Defence, 305
— Royal, of Medicine in wartime, 238
Stomach at work, 397
Surgery, psychiatric implications of, 819
Switzerland, chemotherapy in, 333
Threadworm, the ubiquitous, 649
Tonsillectomy, health and, 334
Toxoplasma in man, 753
Tropics, control of disease in, 651
U.S.A.: Social welfare in, 458
Uterus, ergot alkaloids and involution of, 270
Venereal diseases problem in Canada, 80
Vitamin B deficiency, induced, in man, 488
— C and cooking, 271
— D: Massive therapy in rickets, 517
War and the Press, 46
Wellcome museums, 46
Worms, diet of, 333
- Anthrax, sixty cases of (H. Gold), 201
Antifreeze for doctors, 662
Antitoxin, gas-gangrene, therapeutic value of (M. G. Macfarlane), 636 (O); leading article, 648
Anuria, sulphapyridine: Successfully treated by ureteric catheterization (J. P. Cunliffe), 11—Two cases of, due to sulphapyridine calculi, successfully treated by ureteric catheterization (H. Burroughs and A. G. Johnston), 508 (O)
ANWYL-DAVIES, T.: Cerebral reaction to anti-syphilitic therapy, 20
Anxiety: Night sweats and, 61—Anxiety states in the Navy (G. V. Stephenson and Kenneth Cameron), 603 (O); correspondence, 687
Aorta, coarctation of, 3
— abdominal, arteriosclerotic aneurysm of, with perforation into upper jejunum (W. Hausmann), 362
Appointments, 124, 286, 316, 596, 664, 836
ARBOGAST, J. L. (and H. H. Asst): Observations on 21 cases of infectious mononucleosis, 714
ARCHER, G. T. L. (and others): Endemic typhus fever in Diego Suarez, Madagascar, 506 (O)
Area, surface, measuring, 770
Ariboflavin syndrome (leading article), 109; correspondence, 279. See also Riboflavin
Armistead, Hugh Wells, obituary notice of, 121
ARMSTRONG, E. F.: Rock phosphate in sewage, 34
— G. W.: Internal fixation by screw in oblique fractures of fibula, 115
— Katharine F. (and Alice M. Jackson): Teaching in Schools of Nursing, 330
- ARMY:
Detention barracks, soldier's death in, 91, 155, 835
Discharge from, reasons for, 155
Dyspepsia and peptic ulcer in the Army (Sir Henry Tidy), 473 (O); correspondence, 556
Helmet, steel, 833
Inoculation against typhus, 469
Medical Services, 563
— specialists in, 155
Mental health of recruits, 186
Night vision in the Army: report of 10,333 tests (A. Lister and J. W. Bishop), 325 (O)
- ARNOLD, A.: Regional anaesthesia, 660
AROV, Dr.: Use of spirogyra instead of cotton-wool, 115
Arsenic: For Vincent's infection, 360, 433, 464, 622, 729, 763—Antidotes to (leading article), 681
Arsenical compounds, 413
— encephalopathy, 465
Arsine poisoning (annotation), 785
Arterial spasm, traumatic (C. W. Clark), 167 (O)
Arteries, in essential hypertension, 1
Arteriosclerosis, 573
Artery, innominate, gunshot wound of (G. F. Langley), 711 (O); correspondence, 793, 831
— correction, 804
— pulmonary, case of congenital dilatation of (H. L. Heimann and M. M. Posel), 512 (O)
Arthritis: Pyrotherapy for, 288—At menopause, 501
— gonococcal, treatment of, 566
— spinal, differential diagnosis of, in young subjects (C. W. Buckley), 4 (O); correspondence, 179
ARTHUR, W. G. (and L. A. N. Line): Film of first-aid post during raids, 702
Artificial respiration, rocking device for (J. H. Lahiff), 42
Aschheim-Zondek test, 254
Ascites: Treatment of, 29—In case of malignant ovary, 665
- Ascorbic acid, glucose, and insulin, in treatment of infective hepatitis (D. R. Macdonald), 261 (O)
— in idiopathic methaemoglobinemia (Royal Academy of Medicine in Ireland), 336
ASHL, H. H. (and J. L. ARBOGAST): Observations on 21 cases of infectious mononucleosis, 714
ASHFORD, C. A.: Acid haematin method for estimation of haemoglobin, 575 (O)
Aspirin and gastric haemorrhage, 57; correspondence, 117
Aspland, W. H. Graham, obituary notice of, 696
Association, American, of the History of Medicine: William Osler medal awarded, 699
— Medical: Medals and Awards, 124, 409—President elected, 378
— Pharmaceutical Manufacturers: Award of Distinction to Profs. Fleming and Florey, 836
— of Anaesthetists of Great Britain and Ireland: Annual general meeting, 656
— British, for Advancement of Science: No. 8 of official publication, *The Advancement of Science*, 393

THE CIRCULATION IN ARTERIAL HYPERTENSION*

BY

G. W. PICKERING, M.A., M.B., F.R.C.P.

Professor of Medicine in the University of London; Director of the Medical Clinic, St. Mary's Hospital Medical School

LECTURE II

In Lecture I it was seen that the circulatory changes which give rise to raised arterial pressure are not quite the same in the various diseases of which hypertension is a symptom.

In one type, of which essential hypertension is the chief example, the hypertension is due to arteriolar constriction; evidence of vasoconstriction has been found in the skin and in the efferent glomerular arteries of the kidney, and in both places it has been shown to be of non-nervous origin. In the skin the vasoconstriction is of an order such that when nervous vasoconstrictor tone is removed the skin blood-flow is, for that circumstance, normal or but slightly reduced. A balance-sheet of the circulation suggests that the vessels to most other tissues except muscle are also constricted; and, although there is no evidence as to the nature of the vasoconstrictor agent in these tissues, it is not likely to be different. So far as we know, constriction of the aorta and chronic nephritis present a picture similar in its broad features to that of essential hypertension. In particular in nephritis, our information is less complete.

The second type is that of acute nephritis in which no vasoconstriction has been demonstrated in the skin of the hand and which the renal blood-flow may not be reduced. The circulation in pregnancy toxæmia presents certain features which resemble that in acute nephritis, but there is still too little information to judge of its identity.

We may now proceed to consider to what extent these features of the circulation in hypertension can be reproduced by the activity of known pressor mechanisms.

The Vasomotor Nerves

Like most other unexplained disturbances of the circulation, hypertension, and particularly essential hypertension, has been ascribed to abnormal activity, in this case overaction, of the sympathetic nerves. This overactivity, when it has been accounted for, has in its turn been attributed either to a disturbance in the higher functions of the brain acting on the vasomotor centre or to a diminution in the sensitivity of the carotid sinus and depressor reflexes. The first of these hypotheses has never received any substantial proof: the alleged hereditary element in the aetiology of essential hypertension is compatible with it, but also with other hypotheses. The second hypothesis seemed to receive support when it was demonstrated that in the experimental animal a persistent hypertension could be produced by section of both carotid sinus and depressor nerves (Koch, Mies, and Nordmann, 1927). But Pickering, Rothschild, and Kissin were able to show in 1936 that the carotid sinus mechanism is active in essential hypertension, and the tachycardia which is a cardinal feature of the experimental lesion is absent in the supposed human example.

Most of the evidence with which the vasomotor nervous hypothesis of essential hypertension has been supported proves on critical inquiry no more than that the vasomotor nerves are active in patients suffering from the disease, as they are in normal subjects; and although there is a good deal of normal

variation in the responses to vasomotor reflexes there is no true evidence of their overactivity in hypertension.

From the evidence presented in the first lecture it is improbable that the vasoconstriction which underlies essential hypertension is of nervous origin; for we saw that the vasoconstriction present in hand and kidney is not of nervous origin. In fact, a review of the circulation in the several diseases revealed only one—acute nephritis—in which overaction of the vasomotor nerves seemed likely; and although Arnott and Kellar (1936) have found that in experimental acute nephritis hypertension is prevented by renal denervation no relevant reflex mechanism has yet been demonstrated.

Adrenaline

Adrenaline, first demonstrated by Oliver and Schäfer in 1894, proved a relatively simple substance, and a good deal is known of its action on the circulation of animals though much less of its action on man. Rein (1931) was, so far as I know, the first to point out that the most important action of adrenaline was that of a redistributor of blood, diverting it from gut and skin to muscle, brain, and heart. This is probably also its chief action in man (see, for example, Grant and Pearson, 1937-8). Thus in an unpublished experiment on myself on Dec. 12, 1936, adrenaline infused into the internal saphenous vein, at the rate of 1.6 c.c.m. of a 1:100,000 solution per min., reduced heat elimination of one hand from an average of 224 cal. per min. to 35 cal. per min. while increasing the flow through the other forearm from 4.6 to 7.2 c.c.m. per min. This dose of adrenaline therefore very considerably decreased blood-flow through skin while increasing it through the whole forearm and therefore through muscle; on another occasion in the same subject the arterial pressure was 120/75 before and 145/65 during infusion at a similar rate. We can, I think, be reasonably sure that adrenaline is not concerned in the genesis of the forms of hypertension considered in the previous lecture; for, although it seems to produce constriction of the efferent arterioles of the kidney, as Smith and his colleagues have shown, its constriction of the skin vessels is much too intense for the active agent in any essential hypertension. The simplest demonstration that it is not concerned in essential or chronic nephritic hypertension is one which Kissin and I described in 1936. It is common knowledge that the skin of the face is pink or red in many patients with essential hypertension and in some with chronic nephritis. The absence of constriction in these skin vessels indicates either that there is no excess of adrenaline circulating or that the vessels are insusceptible to it. We were able to exclude the second alternative, for we found that in both these kinds of hypertension the facial skin paled to a normal extent on intravenous injection of small amounts of adrenaline (2 to 2.5 γ).

There is, however, one form of hypertension not yet mentioned in which the presence of abnormal amounts of adrenaline in the circulating blood is the cause of the raised arterial pressure. This is the rare paroxysmal hypertension produced by a pheochromocytoma, a tumour of the adrenal medulla. In this condition occur paroxysms characterized by pallor and coldness of the skin, by hypertension, and in some cases by acute oedema of the lungs; between the attacks the patient is

* An abridged version of the Oliver-Sharpey Lectures delivered before the Royal College of Physicians of London on March 23 and 25, 1943.

In man the action of renin on the circulating fully investigated because animal renin fails to convert angiotensinogen and is therefore inactive in man. The kidneys are a poor source of renin. But hypertension is prepared by Helmer and Page in a form suitable for man, and its effects have been investigated by Kohlstaedt, and Page (1941), Bradley and Page (1941), and Wilkins and Duncan (1941). Hypertension by infusion produces a rise in systolic blood pressure, and a slowing of the pulse which is observed in the infusions. The cardiac output is increased, and the venous pressure is increased. The cardiac output is increased, and the venous pressure is increased, and the venous pressure is increased. Kohlstaedt, and Page state that, unlike adrenaline, it produces no paling of the skin, but Wilkins and Duncan observe this. No measurements of blood flow have been made with the influence of the vasoconstrictor, but Wilkins and Duncan tabulate the flow through the hand of the warm subject in which hypertensin was injected intravenously.

blood-flow after hypertensin varied between limits above & below the resting; in 8 it was increased and in 6 decreased. Although a final conclusion should await a more deliberately planned experiment, these results suggest that the hypertension induced by hypertensin is not accompanied by any pronounced change in skin blood-flow. The effect of hypertensin on the renal circulation has been investigated by Corcoran, Kohlstaedt, & Page by the methods mentioned in the previous lecture. Hypertensin in doses sufficient to raise the arterial pressure about 40 mm. Hg reduces the effective renal blood-flow by about 50%, but lowers the glomerular filtration rate to a much less extent—changes which are attributed to efferent glomerular vasoconstriction.

Wilkins and Duncan concluded from their investigations that the changes produced in man by intravenous injection of hypertensin resembled most closely the hypertension of severe acute nephritis in that both may show the manifestations of cardiac failure—i.e., dilatation of the heart and raised venous pressure, features not observed in essential hypertension except in the terminal stages. These changes are, however, precisely the changes induced in a normal heart by a sudden rise of arterial pressure, as Starling showed decisively on the heart-lung preparation 30 years ago. That the heart may behave similarly in acute nephritis and after the injection of hypertensin would thus seem to be due to their both representing the behaviour of a normal heart to an acute hypertension; and the difference in the behaviour of the heart in the chronic hypertensions is readily linked with its pronounced hypertrophy in such conditions. So far as we know them, the changes in the peripheral vessels in acute nephritis are not the same as those after injection of hypertensin. Thus as yet there is no evidence of any humoral vasoconstriction in the skin vessels in acute nephritis nor of efferent glomerular constriction, both of which are produced by hypertensin. The absence of efferent glomerular constriction in pregnancy toxæmia again excludes this agent in that condition.

But in essential hypertension, and probably in the other related forms of persistent hypertension mentioned in the first lecture, the chief changes noted in the behaviour of the vessels are similar to those induced by hypertensin, which alone of the known pressor substances is a conceivable causative agent. For although, as Goldring, Chasis, Ranges, and Smith have pointed out, a variety of agents such as adrenaline and tyramine, as well as renin and hypertensin, produce constriction of the efferent glomerular arteries of the kidney, only renin and its product hypertensin produce hypertension without so constricting the vessels of the skin that much blood is diverted from it. So far as our knowledge goes—and it is clearly incomplete—they are the only agents known which reproduce the circulatory conditions of essential hypertension. Since there is thus a prima facie case for the view that the renin-hypertensin system may be concerned in the genesis of essential and related forms of human hypertension, we may proceed to examine it in greater detail.

Renin, as Tigerstedt and Bergman showed, is found in the cortex and not in the medulla of kidney; it has not been obtained from any tissue other than renal cortex. It is present in all mammals and birds examined, but not in cold-blooded vertebrates. Prinzmetal and I found that it is destroyed at 60° C., by strong acids and alkalis, and by alcohol above freezing-point but not at -10° C.; it is non-dialysable, salts out in the globulin protein fraction, and is probably a protein. It is an extremely unstable substance, and Butler and I found it became so progressively when purified. It has not been isolated.

Hypertensinogen, the name given to the substrate on which renin acts, is also a protein, and is found only in plasma. It is also a globulin (Muñoz *et al.*, 1940). Evidence from animal experiments suggests that the liver (Page *et al.*, 1941) and adrenals (Houssay and Dexter, 1942) may be concerned in its production, but the part, if any, played by other organs is obscure.

Hypertensin, the product of the reaction of the foregoing, is a simpler substance than either. It is stable to heat, dialysable, and soluble in alcohol (Page and Helmer, 1940a; Braun-Menendez *et al.*, 1940). It is destroyed by peptic or tryptic

digestion, and is therefore thought to be a proteose or polypeptide (Muñoz *et al.*, 1940; Edman *et al.*, 1942).

In a simple mixture of the two renin acts as an enzyme and hypertensinogen as the substrate (Muñoz *et al.*, 1940). That is to say, the amount of hypertensin produced in unlimited time is determined only by the amount of hypertensinogen, and during the reaction hypertensinogen disappears while renin remains. The amount of renin determines only the rate of the reaction. It is obvious, therefore, that the amount of hypertensinogen available is an important factor in determining the intensity of the response to renin, and *in vivo* no response to renin is obtained if the hypertensinogen has been used up (Page, 1939). In the intact animal the amount of renin entering the circulation is also an important factor, for Prinzmetal and I (1938) found the response to renin injected intravenously was proportional to the logarithm of the dose. The intact animal may also be affected by agencies which destroy renin and hypertensin. In 1942 Prinzmetal, Kelsall, and I showed that renin injected intravenously into rabbits could be recovered from the arterial blood after ten minutes but not after an hour, and that the lost renin could not be recovered from the tissues, nor was it destroyed in that time by blood *in vitro*. It is probably slowly destroyed by the tissues, but in a manner at present unknown. Hypertensin is destroyed by an enzyme, hypertensinase, which is most abundant in extracts of kidney and gut, and least in plasma (Houssay and Braun-Menendez, 1942).

Role of the Renin-Hypertensin System

It is probable that the renin-hypertensin system is the effector mechanism in experimental hypertension resulting from renal-artery constriction, for the cumulative efforts of many workers (see Blalock, 1940) have excluded a cause other than chemical, and renin has been demonstrated in the renal-vein blood after renal-artery constriction (see Houssay and Braun-Menendez, 1942). Nevertheless some facts are not easy to reconcile with the hypothesis (Taggart and Drury, 1940; Dock, Shidler, and Moy, 1942), and the chapter is by no means closed. In man there is little direct evidence for the participation of the renin-hypertensin system in hypertension, but the absence of positive evidence does not invalidate the hypothesis. Thus in man it was shown that transfusion of blood from patients with essential or malignant hypertension does not raise the pressure of the recipients (Pickering, 1935-6; Prinzmetal and Friedman, 1936): the same is true in the dog with experimental hypertension (Collins and Hoffbauer, 1937), unless massive cross-transfusions are used (Solandt *et al.*, 1940). The kidneys of patients with benign essential and chronic nephritic hypertension seem to have a renin content no higher than normal (Landis, 1941), but the kidneys of rabbits with chronic hypertension due to renal-artery constriction also have a normal renin content (Pickering, Prinzmetal, and Kelsall, 1942). The crucial test for the presence of renin in the renal-vein blood in man has yet to be performed with the methods successful in the dog.

We may now consider very briefly a further aspect of the hypothesis and inquire whether there is any condition present in essential hypertension which might lead to the liberation of renin from the kidney. Here again the facts are few, and what follows is to be regarded purely as a contribution to a working hypothesis.

The constant presence of renin in the kidney of most mammals examined, and its enzyme-like action on blood, suggest that it performs a definite function in the animal economy. Accepting the interpretation of inulin and diodrast clearances, the chief action of renin or hypertensin on the kidney is to constrict the efferent glomerular arterioles,* and on the circulation to raise arterial pressure without greatly influencing the distribution of blood to organs other than the kidney. Thus we see that the renin-hypertensin system raises intraglomerular pressure by its action both on the renal vessels and on the circulation generally. I would suggest, therefore, that the func-

* Prinzmetal and I (Pickering and Prinzmetal, 1940) found that small doses of renin in the unanesthetized rabbit reduce urine-flow and the creatinine-clearance rate. With larger doses, well above the threshold for the pressor effect, renin produces a pronounced diuresis, in which the sodium and chloride contents of the urine approximate to those of plasma. The significance of this finding is not yet apparent.

The interesting calculation has been made that 5 million people is equivalent to 17,000 tons of meat a year. This, as Dr. E. F. Armstrong points out (1943), happens to be the quantity present in the meat from New Zealand. According to him, Great Britain gets rid in the form of sewage of 150,000 tons of rock phosphate, most of which is population of the United States rejects in equivalent of 60 million tons of rock phosphate. The supplies of phosphate are limited in amount and many of the agricultural soils of the world are with a consequent impairment to their crop

CHEMOTHERAPY OF INTESTINAL INFECTIONS TREATED WITH SULPHONAMIDE COMPOUNDS

BY

AUSTIN C. CLAY, M.D. *Aberd.**Senior Resident Physician, City (Infectious Diseases) Hospital,
Aberdeen*

Sulphaguanidine was originally discovered by Buttle in 1938, but little attention was paid to it until the further researches of Marshall *et al.* in 1940 emphasized its solubility yet poor absorption from the gastro-intestinal tract, and thus presented a new principle in the treatment of intestinal infections somewhat analogous to the use of sulphanilamide derivatives as urinary antiseptics. This was confirmed by Roblin and Winnek (1940). It was used with success by Marshall and his colleagues (1941) in the treatment of acute bacillary dysentery in children in the Harriet Lane Home, New York; and Lyon (1941) described his findings in a group of 23 cases, which were compared with a similar number of controls. Subsequently Anderson and Cruickshank (1941) reported the successful treatment of 41 adult cases of Flexner dysentery, which were compared with a series of 55 control cases in the same epidemic. Fairley and Boyd (1942, 1943) published their observations on some 500 cases treated in the Middle East, the bulk of which were Shiga infections, although a number of cases of Flexner, Schmitz, and Sonne infections were also successfully treated. Bulmer and Priest (1942) and Brewer (1943) have also reported their findings. 76 and 77 cases respectively in the same sphere of military operations. Hall (1941) recorded the successful treatment of 20 cases of typhoid fever with sulphaguanidine, while Levi and Willen (1941) reported the successful treatment with sulphaguanidine of a typhoid carrier who had remained positive after cholecystectomy. Canizares and Morris (1941) made a study of 6 patients with proctitis due to lymphogranuloma venereum in whose condition some improvement was effected by means of sulphaguanidine prior to surgical intervention; while Firor and Jonas (1941) suggested that it might be successfully used in chronic ulcerative conditions of the bowel. Firor and Poth (1941) used it pre-operatively to reduce coliform organisms in the large intestine of patients submitted to colonic surgery. Henderson (1943) has recently recorded the excellent results achieved with sulphaguanidine in epidemic gastro-enteritis of the newborn.

Clinical Findings

During 1941 and the first six months of 1942 there were treated in the City Hospital, Aberdeen, 273 cases of bacillary dysentery, all of which were proved bacteriologically. Of these, 140 were given no chemotherapy but saline treatment only, 83 were treated with sulphaguanidine, and 50 were treated with sulphanilamide. Unfortunately, it was not possible to run the three series concurrently. Specimens of stool were examined twice weekly for organisms, and the blood sedimentation rate was taken on admittance to hospital and at the completion of the course in those receiving drug therapy. The cases under review comprise Flexner and Sonne infections, and were, on the whole, of a mild character, with seldom more than 5 or 6 stools a day, some of which contained blood and mucus and others merely mucus, while some were simply loose. All cases showing blood and mucus in the stools were classified as "acute," while those with loose stools were classified as "convalescent carrier cases." Low-grade pyrexia with minor signs of dehydration and occasional vomiting was observed in the 140 cases receiving no chemotherapy. Of 24 who on admission could be described as acutely ill 6 died, two of the deaths being attributable to intercurrent disease. Where necessary, parenteral fluid was given intravenously in the form

of 5% glucose-saline, but, so far as was possible, patients were encouraged to take fluid by mouth, the quantity aimed at being 8 to 10 pints in 24 hours for adults and proportionately less for children. Throughout, the customary general nursing measures were employed.

Dosage

Sulphaguanidine.—The dosage used was an initial loading dose of 0.5 g. per kilo of body weight for the first 24 hours, followed by a maintenance dose of 0.1 g. for the next 4 days. The tablets were powdered, and were administered in milk 4-hourly for the first 24 hours and thereafter 3 times daily for 4 days.

Sulphanilamide.—The following doses were given 4-hourly for the first 4 days and 3 times daily for a further 4 days, each tablet containing 0.5 g.:

0-3 months	1 tablet
3 months-2 years	1½ "
2-5 years	2 "
5-10 "	4 "
10-15 "	1½ tablets
Over 15 years	2 "

No Chemotherapy.—Adult patients were given 2 drachms of sodium sulphate night and morning, and child patients 1 drachm night and morning.

At the end of the first 24 hours the drug content in faeces and blood was estimated and the blood sedimentation rate was also determined. Similarly, when a patient became bacteriologically negative the blood sedimentation rate was again taken. Specimens of stool were examined twice weekly until three consecutive negative results were obtained. In no case were rectal swabs taken; nor were the faeces mixed before obtaining specimens, these being taken purely at random.

Analysis of Flexner Cases

Flexner Cases treated with Sulphaguanidine.—Forty-seven cases were treated; the average duration of stay in hospital was 13.4 days and the average number of days before becoming bacteriologically negative was 6.6. These were subdivided into 13 acute cases and 34 convalescent carriers.

Flexner Cases treated with Sulphanilamide.—Twenty-one cases were treated; the average duration of stay in hospital was 30.4 days and the average number of days before becoming bacteriologically negative was 20.9. Eleven cases were regarded as acute and 10 as convalescent carriers.

Flexner Cases—No Chemotherapy.—Eighty-three cases were treated without chemotherapy; the average duration of stay in hospital was 22.7 days, while the average number of days before becoming bacteriologically negative was 13.3. These were subdivided into 63 acute cases and 20 convalescent carriers.

Analysis of Sonne Cases

Sonne Cases treated with Sulphaguanidine.—Thirty-six cases were treated; the average duration of stay in hospital was 17.1 days and the average number of days before becoming bacteriologically negative was 10.3. These were divided into 16 acute cases and 20 convalescent carriers.

Comparative Results of Chemotherapy

Treatment		Flexner			Sonne		
		Acute	Conv. Carr.	All Cases	Acute	Conv. Carr.	All Cases
Sulphaguanidine	No. of cases	13	34	47	16	20	36
	Average days in hospital	12	13.9	13.4	12.1	21	17.1
	Average days bacteriologically positive	4.6	7.4	6.6	5.9	14.3	10.3
Sulphanilamide	No. of cases	11	10	21	9	20	29
	Average days in hospital	28.8	32.2	30.4	26.1	22.8	23.8
	Average days bacteriologically positive	19	23.1	20.9	16.3	13.4	13.9
No chemotherapy	No. of cases	63	20	83	18	39	57
	Average days in hospital	23.4	20.5	22.7	19.4	18.8	19
	Average days bacteriologically positive	14	10.5	13.3	9.9	9.4	9.5

Sonne Cases treated with Sulphanilamide.—Twenty-nine cases were treated; the average duration of stay in hospital was 23.8 days, while the average number of days before becoming bacteriologically negative was 13.9. These cases were divided into 9 acute cases and 20 convalescent carriers.

Sonne Cases—No Chemotherapy.—Fifty-seven cases were treated; the average duration of stay in hospital was 19 days, while the average number of days before becoming bacteriologically negative was 9.5. These were divided into 18 acute cases and 39 convalescent carriers.

Biochemical Findings

Sulphaguanidine.—Blood concentrations usually varied from 3 mg. per 100 c.cm. to a trace, but in one case 9 mg. was found, in 2 cases 8 mg., in 1 case 7 mg., and in one other case 6 mg. per 100 c.cm. The concentration in faeces varied from a trace to as high as 10,000 mg. per 100 c.cm. At the beginning of the series leucocyte counts were done as a routine in each case, but as these were invariably normal this examination was discontinued.

Sulphanilamide.—Blood concentrations were lower than in the case of sulphaguanidine-treated cases, the highest concentration in the blood being 3.3 mg. and the lowest 0.1 mg. per 100 c.cm. In the main they varied between 1 and 2 mg. Concentrations in the faeces varied between a trace and 840 mg. per 100 c.cm., the average being between 300 and 400 mg.

Toxicity of Drugs

In no case treated with either sulphaguanidine or sulphanilamide was any evidence of toxicity observed, judged by the standards of nausea, cyanosis, vomiting, pyrexia, rash, or haematuria. The urine was examined every second day for blood and albumin, but this practice was later reduced to twice weekly on account of lack of toxic symptoms. Older patients were also questioned with regard to any disagreeable effects, but these were remarkable by their absence.

Gastro-enteritis in Infants

Four cases were treated with sulphaguanidine; 3 of these patients died without any improvement in the stools or in the general condition. All were male babies, varying in age from 1 to 2 months and presenting varying degrees of dehydration, with frequent loose, green, and offensive stools from which no specific organism was obtained. The dosage used was 3 g. during the first 24 hours as a loading dose, followed by 2 g. daily for 4 days, but in none of the cases did the concentration in the blood exceed 0.8 mg. per 100 c.cm., although the concentration in the faeces went as high as 25,000 mg. We can only conclude that the dehydration and the frequency of the stools were so pronounced that the drug had no time to be absorbed and was passed rapidly through the intestines.

Paratyphoid B Fever

Eight cases treated with sulphaguanidine were taken, varying in age from 3 months to 53 years. Sulphaguanidine had no effect on the stools, which remained positive throughout the course and for a considerable time afterwards, although in two cases a distinct improvement in clinical condition was noted. These patients were exceedingly listless, with marked loss of appetite, but within 48 hours of starting treatment with sulphaguanidine their general condition had greatly improved. The dosage varied from 5.25 g. daily for 6 days to a maximum of 10.5 g. daily for 14 days.

Summary

273 cases of bacillary dysentery treated in the City (Infectious Diseases) Hospital, Aberdeen, during 1941-2 are described, together with 4 cases of gastro-enteritis of infants and 8 cases of paratyphoid B fever. Of the cases of bacillary dysentery 140 received no drug, 83 were treated with sulphaguanidine, and 50 had sulphanilamide.

The series receiving no chemotherapy were given 2 drachms of sodium sulphate night and morning for an adult and 1 drachm night and morning for a child. Those receiving sulphaguanidine were given a 5-day course based on body weight, the initial loading dose during the first 24 hours being 0.5 g. per kilo of body weight, followed by a maintenance dose of 0.1 g. per kilo for the next 4 days. Those receiving sulphanilamide were given a dosage amounting to half the quantity of sulphaguanidine.

The tablets were powdered and administered in milk 4-hourly for the first 24 hours and 3 times daily for the next 4 days. Parenteral

fluids were given intravenously in the form of 5% solution where necessary, and particular stress was laid on fluid intake—mouth—8 to 10 pints for adults and proportionately less for children.

The stay in hospital and the number of days during which stools remained positive were reduced by half in the sulphaguanidine-treated cases as compared with those receiving no chemotherapy, except in the case of Sonne convalescent carriers, in which the stay in hospital and the number of days bacteriologically positive were slightly increased. In the sulphanilamide-treated cases the stay in hospital and the length of time during which stools remained positive were increased, but this may be accounted for by the dosage of drug and by the small number of cases treated.

Neither sulphaguanidine nor sulphanilamide produced any symptoms or disagreeable effects.

4 cases of gastro-enteritis and 8 cases of paratyphoid B fever were treated with sulphaguanidine without any improvement.

I am indebted to Dr. Prescott of the Wellcome Foundation for very kindly made available the necessary supplies of sulphaguanidine and wish to thank Dr. John Smith, Director of the City Laboratory, for his interest and co-operation in this investigation.

TECHNIQUE OF INTRAVENOUS DRIP TRANSFUSION IN INFANTS

BY

D. MacCARTHY, M.D., M.R.C.P., D.C.H.

Late Registrar, Hospital for Sick Children, Great Ormond Street

The technique of intravenous drip transfusion, or clysis, was first applied to the treatment of infants ten years ago, since when it has established itself as the most effective method of combating severe dehydration due to infantile diarrhoea and vomiting or for the operative administration of fluids in babies and children. But it is much more difficult to carry out in adults, has more risks, and provides an arduous task for the nursing staff, on whose energies and competence the success of the method chiefly depends. Unfortunately owing to the frequency with which things can go wrong it is apt to be regarded as a method that demands a team of experts to run it. It is true there is a real danger of overloading the system with fluid, and judgment in the matter requires experience; but it is as often as not the accumulation of small faults and mishaps, rather than serious ones, that determines the success or failure of an undertaking. The object of this paper is to discuss causes of failure and their remedy and to put forward general principles for running continuous intravenous transfusions in infants with efficiency and safety.

The Technique Normally Adopted

The anterior saphenous vein at the ankle is chosen as it is very constant in position and has definite surface markings. It lies on the anterior surface of the tibia, running downwards and slightly backwards midway between the tendon of the anterior tibial and the internal malleolus of the tibia, both of which can be felt. It is often visible in thin babies or may be made visible by standing out, and it is plainly visible in most adults in its position and course may be easily examined.

The diameter of this vein in a 3-months-old baby is about 1 and 2 mm., and although it will stretch to slightly more than this it is difficult to insert a cannula into it of greater than 2 mm. Various types of cannula are used to this case, such as a large-sized hypodermic needle with the

off, a ureteric catheter (Wilmers, 1938), a hypodermic needle covered by a closely fitting length of ureteric catheter, a small-sized Hamilton Bailey needle, or the needle specially designed for the purpose by Bateman, with an inner cannula which can be removed and cleaned should it become blocked.

The foot and leg are firmly fixed by strapping to a padded lint applied to the outer side of the leg. The foot is fixed in a position of slight plantar flexion (Fig. 1). The skin between the internal malleolus and the tendon of tibialis anticus is anesthetized with local anaesthetic: 0.5 c.cm. of 1% novocain usually enough for this, but another 0.5 c.cm. may be injected more deeply. A transverse incision about half an inch long then made at right angles to the axis of the vein at the level of the internal malleolus. The vein, which may be difficult to see if there is much oozing, is identified by its bluish or pinkish colour, and is dissected free from its fascia so that no ligatures, about a quarter of an inch apart, can be passed over it. The distal ligature is tied immediately.

The vein is opened by an oblique or transverse scissor-cut, in the technique for adults, and the cannula inserted and fixed in with the proximal ligature. Obviously in such a tenuous vessel some care is required to cut a hole big enough to admit the cannula and yet not snip the vein clean in half. It is this, in finding the vein, that constitute the chief difficulty of the operation.

One c.cm. of normal saline should now be injected through the cannula. If the latter is in the vein the saline will go in with the lightest pressure on the plunger; but if it is in the sheath of the vein, or in the soft tissues or some fascial tissue it was mistaken for a vein, pressure will be required and a bump will appear under the skin. All being well, the incision closed by one stitch, and the tubing carrying the transfusing fluid from the vacoliter is connected to the cannula by a well-fitting adapter nozzle and secured in position by strapping; the flow of fluid is then started, the rate being controlled by screw clamp and drip connexion.

Some Dangers, Difficulties, and Mistakes

1. Severe or Fatal Collapse at the Start.—An intravenous drip could never be regarded as an emergency. It may be very gentle and a life-saving measure in an acutely dehydrated infant, but often in such cases a condition analogous to shock is present, due to anhydreaemia and toxæmia, and the process of setting up the drip, however skilfully done, may be more than the infant can stand. There is no case that will not be better off in these circumstances by being given a hot bath, or taken into a warmed bed, and left severely alone for one or two hours. At the end of this time it will probably be able to stand such intervention as is necessary to start the transfusion.

2. Excessive Time Spent in Setting up the Drip, with Consequent Exhaustion of the Infant and Deterioration of its General Condition.—The baby may be relieved of much strain by dividing the whole process into three stages. When it is decided to give an intravenous drip (i.e., on admission or when amining the infant in the ward) a time should be chosen which suits the ward and the doctor (within a few hours, of course; there is never more urgency than this); but the preliminaries of splinting, cleaning, and tying the limb should be carried out forthwith. The baby is then left in peace for an hour or more, and may get to sleep in the ensuing interval until the time of the operation. When that time comes it is rested, and part of the procedure is already completed.

In the second stage the instruments, vacoliter, etc., which have been prepared are brought to the very last degree of readiness at the bedside, the infant as yet being completely undisturbed. The vacoliter must be suspended, tubing filled and saline dripping from the cannula, aneurysm needle threaded, stitch ready, and small strips of strapping available for fixing the cannula and tubing in position. The tightness of the adapter fittings must be tested, also the points of the scissors. To insert the cannula it is necessary to cut half-way through a vein which may be only 1 mm. thick, so it is important to make sure that the tips of the scissors will do their job.

In the third stage the bedclothes are gently lifted back, the limb all ready, and the dissection of the vein is begun. When quickly and neatly done the baby suffers very little fatigue, and may even sleep through it. But if the three

stages described are made one procedure and there are any minor mishaps or delays, as there often are, the total time spent on the job is much longer for the baby, and in the end an hour or more may elapse before it is once again left in peace. By this time it may be very exhausted.

As to the actual dissection of the vein, only practice can bring speed, but it is worth while for the inexperienced to note that the vein is more easily seen when a local anaesthetic is injected into and deep to the subcutaneous tissue, as its blueness then contrasts with the pale injected tissues and oozing is diminished. About 1 c.cm. of 1% novocain in all may be used. If the subcutaneous tissue is widely split at right angles to the incision by opening the points of the scissors, it can be identified at once, but it is less and less easily discerned when the tissues become blood-stained from frequent swabbing and tentative probing. In plump babies there need be no fear of severing the vein in cutting through subcutaneous tissue, as it lies well down on the deep fascia. It is easier to insert the cannula into very small veins if the stylet is in, as this projects beyond the end of the cannula and, being smaller, can be got into the vein first; the cannula can then be slid along the stylet till it also lies in the vein.

3. Venous Spasm.—It is not uncommon for the drip to stop immediately after it is set up or to run excessively slowly at the start. Attempts to correct it there and then only lengthen the time of the whole operation and add to the exhaustion of the child. The temptation to continue manipulations with or syringing through the cannula must be resisted. If the limb is warmed up by hot-water bottles and the whole thing left alone, the drip will nearly always start spontaneously and speed up by itself. Relaxation of venous spasm may be the reason.

4. Clotting.—A double cannula, of which Bateman's needle (Field *et al.*, 1943) is an example, is the only safeguard against this fault. If the inner cannula becomes blocked it can be thoroughly cleaned and replaced without trouble. It is therefore essential to get an outer cannula into the vein first: it may be a tight fit, but it can be done in all but the very smallest veins. One of the causes of clotting has its origin at the time of setting up the drip. Thus, when the outer cannula is inserted into the vein blood may flow back along it. If there is any delay in starting the flow of saline this blood will begin to clot; then when the inner cannula is inserted through this clot a small plug will block the end of it. Although this plug may be driven out at once, any particle remaining will form the starting-point of a firmer clot later on. Therefore a stylet should always be placed in either cannula when saline is not flowing through it even for a few minutes, and the stylet should be in the outer cannula at the time it is introduced.

5. Splinting the Limb.—Nearly all other troubles—for example, irregular dripping, leaking, damage to vein, etc., mentioned below—are due to the limb not being properly immobilized or the fixation of the cannula and tubing being insecure. Splints of several sizes must be available. When an ankle vein is used the splint should project well beyond the

Fig. 1.—Right way. Long splint; tubing supported and approaching the cannula at the right angle, without flexion.

Fig. 2.—Wrong way. Short splint; flexion on tubing, with spring-like strain transmitted to vein.

foot and should have little padding. The foot must be fastened to it most firmly with strapping next the skin. Elastoplast will not do, and a heavily upholstered splint or the limb swathed in cotton-wool and bandages is worse than useless. When properly set up, the splint, leg, cannula, tubing, and dressing, held together by as many strips of strapping as required, form one firm structure. The baby can wave its leg about or be taken out of bed for nursing or lie on either

side—a great advantage, for it sleeps much better on its side. The most important thing is that the splints should be long enough to project 8 to 12 in. beyond the foot, so that the tubing leading to the cannula in the vein may be fastened at the far end of the splint and then have a straight run up towards the vein (Fig. 1). If it is fastened close to the foot the tubing will have flexion on it, the spring-like action of which will be transmitted to the cannula in the vein, and the strain on the wall of the vein may be considerable (Fig. 2). A pad of cotton-wool should support the weight of the tubing and give it the natural curve required to bring it nicely to the vein (Fig. 1). Sometimes the tubing is left unfastened in the most haphazard way, in which case it waggles to and fro and may tear the vein, so that the transfusion becomes a continuous subcutaneous, not an intravenous, drip. The rate of flow varies considerably if the cannula is loosely held in position, as any movement of the foot or tubing may cause it to kink the vein. Also, the endothelium may be damaged and thrombosis occur. A small stitch, through skin only, just distal to the incision, may be used to tie the cannula in position, and is very effective in preventing any lateral or pulling and pushing movement of the cannula in the vein. When the foot is really securely held the baby feels no pain and does not want to move it. But when things are loose its wriggling causes pain and it tries to work the foot looser still. Leaking may then occur between the adapter nozzle and the cannula. This is another cause of irregularity in the rate of the drip, and the discrepancy between the recorded amount run in and the amount the child has really received may be serious. The arm is much easier to control, and for this reason drips in the antecubital veins generally run smoother and longer than others. But these veins may be difficult to find in fat babies unless they can be seen.

The cephalic vein at the wrist, which corresponds anatomically to the anterior saphenous at the ankle, is serviceable in all but the tiniest babies. It runs midway between the styloid process of the radius and the tendon of extensor carpi radialis. The hand should be splinted palm downwards.

Complications

Sepsis should never occur; but it does. The frequency of its occurrence is directly proportional to the amount of interference there has been in the course of the continuous drip. The case that runs smoothly, for several days even, hardly ever gets infected. But when the dressing is frequently lifted and many readjustments are made infection is apt to creep in. Thrombophlebitis is common but very rarely proceeds to suppuration. An abscess sometimes forms, a week or more later, half-way up the calf. A low-grade infection of the incision is quite common. These complications respond well to appropriate measures, but, occurring in infants who are already much debilitated, should always be regarded seriously. Prevention is embodied in the measures described for getting smoother running of the drip.

Oedema.—Local oedema may be due to the strapping being too tight above the site of transfusion, to the drip being too fast, to tearing or thrombosis of the vein; or it may be the first sign of a developing general oedema. General oedema may be due to too much fluid, too much sodium, hypoproteinaemia, nephritis, sclerema, anaemia, vitamin B deficiency, or circulatory failure. Eucortone may also cause it (Ferrebée *et al.*, 1939). With the exception of too much fluid, it is extremely difficult to distinguish clinically between these various causes of general oedema. In any case of general oedema or pulmonary oedema the drip must of course be discontinued at once.

Bronchopneumonia.—This is still regarded as the most serious and most frequent complication of gastro-enteritis, and the blame is often laid on the continuous intravenous drip. But it must be borne in mind that the majority of cases of infantile diarrhoea and vomiting are due to upper respiratory tract infection, and the infecting organisms may show various propensities for invading the lungs and bronchi in different epidemics and different seasons, regardless of whether continuous drips are given or not. However, there is no doubt that nursing a baby for long periods on its back or maintaining a high salt content in the transfusing fluid does favour pulmonary stasis and oedema, leading to infection, whereas

nursing it on its side and with moderate salt content in the fluid does not.

Petechial Rashes.—These occasionally occur in the later stages in cases of gastro-enteritis that have been given several intravenous drips. They begin as very fine speckled petechiae, chiefly on the trunk, and may develop into ecchymoses or large haemorrhagic taches. They are presumably due to capillary damage. The nature of this is uncertain, but it is not scorbutic, as vitamin C does not prevent it or cure it; nor is it likely to be "toxic," as these rashes do not occur at the most toxic stage of the illness, which is usually the beginning. The probable explanation is the strain imposed on the capillary endothelium by the frequent disturbances of blood volume and alterations in blood chemistry occurring during repeated transfusions. The prognostic significance is not as grave as that of haemorrhagic rashes in general infections, but the outlook is usually very bad for other reasons.

Control over Fluid Input

It has already been mentioned that giving too much fluid constitutes a major risk in the application of the technique of intravenous transfusions to infants.—The following general rules provide a reliable safeguard against this danger and will be found to make for good results.

1. The approximate quantity of fluid required in 24 hours must be calculated in advance and put down in writing together with the child's weight as a check for all to see.*

2. The rate at which this fluid is to be given must be expressed not as drops per minute but as ounces (or cubic centimetres) per hour. This needs special emphasis, for the size of a drop varies with the speed at which it falls and the shape of the dropper; also, the rate of dripping is apt to vary while the observer's back is turned, and a period of slow or rapid dripping may go unrecorded. Therefore even if specially calibrated droppers are used it is impossible but this means to foretell how much fluid will be delivered over a given period of time; the rate of the drip is much too variable. The nurse who is controlling the drip must find by trial and error the approximate rate which will deliver a given amount per hour, and periodically adjust it according to her own judgment to keep the input per hour within such limits.

3. There must be reasonably accurate and reasonably punctual hourly recording of the amount run in. An exceptionally large or small input in one hour can then be corrected in the next.

4. The amounts per hour should be added up as the day goes on; it is then easy to see how far the total for the 24 hours is going to exceed or fall short of the required amount, and adjustment of the hourly quantity can be made accordingly. Fluids by mouth must of course be included in the reckoning.† It is more practical to express intravenous fluid in ounces than in cubic centimetres, as this is the unit by which a baby's fluid intake is normally measured and a unit with which all nurses are familiar. The reading of these hourly quantities on the scale is easier and more accurate if the vacoliter or flask is tall and of small diameter. The Baxter type is not very suitable. In practice it will be found that measurement to within a quarter of an ounce is quite easy on the E.M.S. transfusion bottle, and it is not necessary to try to be more accurate than this.

5. *Strength of Saline to be Used.*—It is now widely accepted that the continuous transfusion of normal saline carries with it the danger of producing hydraemia and oedema, as the infant's powers of excreting surplus sodium chloride are limited. Solutions of approximately half-normal saline, on the other hand, are adequate for replacing lost base in any case of diarrhoea and vomiting, and have not this danger of overloading the body fluids with salt.

6. *Occasions for Extra Caution.*—(i) When any degree of circulatory failure is present much greater caution must be used if overloading the heart is to be avoided. (ii) Babies with "toxæmia," whether it be from "alimentary intoxication," pneumonia, otitis media, or any other infection, have difficulty in retaining fluid given parenterally and in adjusting the balance between intracellular and interstitial fluid. They are liable to remain in a state of chronic dehydration even when given full quantities to cover fluid loss. By contrast the non-toxic dehydrated baby—for example, a case requiring fluid after operation or a pyloric stenosis—when given correct amounts will adjust its fluid balance with ease. If the infection can be overcome the same may be expected of the "toxic" baby; but pushing fluids or attempting to adjust blood chloride levels, etc., by varying strengths of saline is unlikely to achieve anything so long as this persists.

* The actual quantities and rates of transfusion, according to weight of baby, are discussed by Field *et al.* (1943).

† All these points are embodied in the daily fluid chart advocated by Field *et al.* (1943).

Conclusion

Nothing perhaps requires greater emphasis in this paper than that all these points concerning technique should be thoroughly understood by the nursing staff. Some of them may seem trivial, but it is only by constant attention to these details that this method of continuous intravenous drip transfusion will consistently give the good results which are justly claimed or it.

TRIGEMINAL NEURALGIA AT AN EXCEPTIONALLY EARLY AGE: CURED BY GASSERIAN ALCOHOL INJECTION

BY

WILFRED HARRIS, M.D., F.R.C.P.

Physician to Maida Vale Hospital for Nervous Diseases; Consulting
 Physician to St. Mary's Hospital

Paroxysmal trigeminal neuralgia—or, better, trigeminal tic—is usually a disease of the latter half of life, four-fifths of all cases starting within the three decades 41–70 and more than one-third in the decade 51–60. Yet occasionally young people are attacked, for I have had more than twenty patients who began to suffer before the age of 21—two of them at the age of 12. The earliest hitherto recorded case in my knowledge is that of a boy aged 10 operated on by Mr. Barclay (1922) of Newcastle.

Case History

I have now to record the case of a girl who had been suffering since the age of 16 months from frequently repeated daily spasms of pain, lasting a few seconds only, and referred to the left lower jaw up to the ear. She was a Caesarean baby, weighing 9 lb. at delivery, and between the ages of 4 and 5 months had won no fewer than four prizes at baby shows. Yet her dentition did not start until she was 12 months old, and from the age of 16 months she began to have obvious pains with her teeth, paroxysms of a few seconds' duration occurring frequently during the day, and often waking her, screaming, at night. At first the neuralgic attacks seemed to affect both sides, until she completed her milk dentition at the age of 3 years—a year later than the average. Since then the attacks have been definitely limited to the left side, being referred along the lower jaw to the ear, and lasting a few seconds only.

She was first brought to me on July 3, 1942, when less than 4½ years old, and on several occasions I witnessed the sudden attacks of pain, lasting only from a few seconds to a quarter of a minute; the child immediately afterwards becoming quite normal in behaviour. Radiographs of the mandible showed no bone or dental abnormality. She had previously been treated at Great Ormond Street Hospital, and drugs seemed to have no influence on the neuralgic spasms, so I decided on alcohol injection of the foramen ovale. This I attempted on Aug. 21 under preliminary rectal paraldehyde and then ethyl chloride inhalation. No co-operation with the little patient was possible by such a method, and the result was not good: anaesthesia of the third division was slight, if any, and freedom from pain lasted only a couple of days. Three other attempts were made under general anaesthesia in September and November, using the lateral route, without obtaining lasting trigeminal anaesthesia, though after the injection on Nov. 18 she had very few attacks of pain for ten days, then relapsing as before. On Dec. 9 I again injected under a general anaesthetic, using the anterior route in front of the coronoid process, and this time produced complete left trigeminal anaesthesia, after injecting 8 minims of 90% alcohol into the Gasserian ganglion. The neuralgic spasms died away within two days, and she has had no further signs of neuralgia up to the present time—seven months after the injection—though some keratitis developed during the last week of December, with some temporary loss of the superficial corneal epithelium. She was taken into Maida Vale Hospital at once, and the keratitis cleared up completely under treatment, and the cornea now shows no sign of opacity or scar. With the exception of a mild attack of German measles while being treated for the keratitis she has remained perfectly well, and, though the trigeminal anaesthesia persists unaltered, the child does not appear to take notice of it, and is quite merry and bright.

Comment

As regards the prognosis, it is quite probable that the cure will be permanent, as I have found in numerous other similar cases in adults. There is a possibility of recurrence of neuralgia on the other side, for I have met with bilateral trigeminal tic in at least 100 cases, and its incidence, in my experience, seems to be between 4 and 5% of the total cases seen. Sometimes the neuralgia appears on both sides within the period of a week, but more often there is an interval of several years. One of my patients, a lady of 64 when I first saw her eighteen years ago, had suffered since the age of 12 with typical neuralgic tic on the right side of the face—that is, for 52 years. Gasserian injection cured that pain completely; but fifteen years later, when she was 79, similar neuralgia attacked the left side, and I had to inject the left Gasserian ganglion also, thus numbing both sides of her face completely. Sixty-seven years therefore separated the onset of the neuralgia on the two sides. The left motor root had recovered after the first Gasserian injection, as is usually the case, and therefore she had no jaw-drop after the second Gasserian injection.

The probability of bilateral pain probably increases with the length of duration of the disease, so that in the case of the child described above, whose pain was at first bilateral, there is a distinct possibility that the pain may recur at some future date on the right side.

As regards the aetiology of trigeminal tic, it is usually stated in medical and neurological textbooks that the cause is unknown. I have for many years been convinced that the cause is an infective neuritis of the trigeminal-nerve endings in the maxilla or mandible, in the large majority of dental origin, though occasionally secondary to antral infection. This view I have consistently taught, and have published on various occasions, with my reasons for this belief (Harris, 1926, 1937, 1940).

In the case of this little child, otherwise very healthy and not in the least degree of neurotic type, the acute onset of the neuralgia with commencement of her teething is most suggestive evidence of the close connexion between dental disturbances and the origin of trigeminal tic.

THE AVAILABILITY OF THE CALCIUM OF MILK

BY

KATHARINE H. COWARD, D.Sc.Lond.

ELSIE W. KASSNER, F.I.C.

AND

LETTITIA W. WALLER

(From the College of the Pharmaceutical Society, London)

The experiment reported here was carried out in response to criticism of our experiments published in this *Journal* (Coward, Kassner, and Waller, 1938). In the early experiments we had shown that rats fed on a diet resembling that of a poorer-class population and supplemented by liberal doses of cod-liver oil failed to produce normal calcification of the bones, but that the calcification was improved in proportion to the supplementary doses of a mixture of calcium and phosphate salts given. In fact, the highest dose of salt mixture produced as high a percentage of ash as did a supply of milk *ad lib.* each day. It was not, however, from a comparison of results of these apparently excessive doses that we drew our conclusion of the relative availability of calcium from milk and from salts, but from the result of giving only 5 ml. of milk to one of the groups of rats. Unfortunately we had not determined the calcium content of the milk given, for this comparison was not the purpose of the experiment. Judging by the percentage of ash found in the bones, however, the milk apparently contained only 0.76 g. of calcium per litre. Since the average calcium content of cow's milk is 1.12 g. per litre, we thought it very unlikely that the sample we used could

* Including an average of 5 mg. from diet plus 1 mg. from drinking-water.

have contained as little as 0.76 g. This led us to wonder whether the calcium of cow's milk was less available to the rat than that of inorganic salts. However, Kon (1938), who summarized the evidence on this point to date, pointed out that we had not taken into account the fact that the rats which had received milk had grown more than those which had received the salt mixture. Gaunt *et al.* (1938), also contended that without figures for the total calcium and phosphorus content of the animals the relative availability of these elements from different sources can only be decided by balance experiments.

We admit that the criterion of calcification should be total ash content of the bones and not the percentage of ash, but we maintain that if equal amounts of calcium from different sources are equally effective in promoting calcification in any bone (or preferably bones), then the calcium in those sources must be equally available to the animal which demonstrated the effectiveness.

We therefore carried out another experiment in which we determined the calcium content of the milk and of representative whole-day rations of the other foods given, and in which we grouped the animals in a manner better suited to this particular comparison. We used as the criterion of calcification the total ash content of the dry fat-free (a) humerus and (b) femur. We found that the total ash content of both bones was very slightly higher, but not significantly so, in the rats given extra calcium in milk than in the rats given equal amounts of calcium as inorganic salts. The calcium in each of these sources supplied from a quarter to two-thirds of the rats' total intake of calcium.

Experimental

Eight litters of six rats each were distributed, litter by litter, into eight groups, the numbers of males and females in each group being equal. Each rat was housed in a separate cage and fed on a diet similar to that of the "poorer class," being given weighed portions of each food daily and slightly more than enough white bread to satisfy appetite. In addition, each rat was given a daily dose of 0.12 g. of cod-liver oil. Supplements given were:

Group 1:	0.02 g. of a calcium and phosphate salt mixture
" 2:	0.04 " " " " " "
" 3:	0.08 " " " " " "
" 4:	3 ml. of pasteurized milk
" 5:	6 ml. " " " " " "
" 6:	9 ml. " " " " " "

London tap-water (Bloomsbury district) was supplied *ad lib.* and the amount taken daily estimated. Each rat was weighed once a week. The calcium contents of a bulked sample of a typical 5-weeks ration for one rat and of the milk given were determined. The experiment was carried on for five weeks. The salt mixture given consisted of:

Disodium hydrogen phosphate, $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$	35.8
Dipotassium hydrogen phosphate, K_2HPO_4	69.6
Calcium phosphate, $\text{Ca}_3(\text{PO}_4)_2 \cdot 4\text{H}_2\text{O}$	68.8
Calcium lactate, $\text{C}_6\text{H}_{10}\text{O}_7\text{Ca}_2$	15.4
	189.6

Results (Summarized in Table)

Increase in Weight of Whole Animal.—The rats given the various doses of the salt mixture increased in weight at almost the same rate—the males at about 11.1 g., the females at the same rate. The response of the rats given graded doses of milk was that of those given the salt mixture, the increase in

weight of the three groups of male rats was 13.4, 15.95, and 16.2 g., and of the three groups of female rats 12.25, 13.4, and 15.0 g. respectively.

Weight of Fat-free Bones (Humeri and Femora).—The dry fat-free bones of the rats given supplements of milk were slightly heavier than those given equal amounts of calcium as inorganic salts, humeri being 5.64% and femora 9.55% heavier.

Weight of Total Ash of Fat-free Bones (Humeri and Femora).—The total ash of the dry fat-free bones of the rats given milk was very slightly heavier than that of the rats given equal amounts of calcium as inorganic salts, the ash of the humeri being 3.68% and that of the femora being 6.58% heavier. Considering that the calcium supplied in the supplements constituted from 25% (lowest dose of salt mixture) to 67% (highest dose of milk) of the total calcium intake, these figures cannot be considered as indicating that the calcium of milk is more easily available than that of inorganic salts.

From these figures it follows that the percentage ash of the bones of the rats receiving milk supplements was less than that of the rats receiving inorganic supplements, the humeri of the "milk" rats containing only 98.15% and the femora only 97.29% of the percentage ash of the "salt mixture" rats. These figures also cannot be considered significant.

Method of Calculating the Results

In order to obtain the ratio between the weight of bones given equal amounts of calcium as (a) milk or (b) inorganic salts, the average of the logarithms of the weight of the bones was plotted against the total calcium intake. (If plotted against the amounts of calcium taken as supplements these lines would be shifted equal distances to the left; the slopes and intercepts apart would not be affected.) The best straight line through each set of three points was determined, the slope of the two lines calculated, lines with this slope drawn through the points with average y and x values, and the distances between them determined. This was the logarithm of the ratio between the weights of the bones of the rats over their intake of calcium.

A similar calculation was made to obtain the ratio between the total ash contents of the bones of the rats.

Summary and Conclusions

Graded doses of (a) milk and (b) a calcium and phosphate salt mixture were given daily to groups of rats, 8 in each group, weeks fed on a "poorer-class" diet liberally supplemented with cod-liver oil for vitamins A and D. Determinations of calcium intake of each group were made. It was found that the dry fat-free humeri and femora of the rats receiving milk were slightly heavier than those of rats receiving inorganic salts.

The ash content of these bones of the "milk" rats was slightly greater than that of the "salt mixture" rats. It follows that the percentage ash in the bones of the rats was slightly less than that of the "salt" mixture rats. None of these differences can be considered significant.

It is realized that the supplements supplied from 25 to 67% of the total calcium intake.

It is concluded that the calcium of milk is not as easily available for calcification to the growing rat as inorganic salt mixture which contains also an adequate amount of phosphorus.

Medical Memoranda

Obstetrical Forceps for Fibroid

Many stories have been told of doctors who in times past have applied forceps to fibroids in the belief that they were foetal heads. I am unaware of any record of a vaginal forceps application to a fibroid being deliberately performed, and as the anaesthesia has on two separate occasions in a relatively short time been of considerable assistance, I believe it may be useful to draw attention to the fact. There is also scope for the use of these instruments during myomectomy by the abdominal route.

CASE RECORD

A woman aged 52, with two children aged 23 and 8, was admitted to an emergency to the Radcliffe Infirmary on March 13, 1943. She was bleeding badly at the time of admission, was very anaemic, and gave a history of recurrent severe losses of progressive amount for the past year. Prior to this, menstruation had been regular, of the 28-day type, and the losses were moderate. For some months there had been progressive difficulty in micturition, with frequency and straining.

On admission the patient had a temperature of 99°, pulse 116, and respiration rate of 22. She was well nourished but very blanched. A firm mass could be felt in the midline, rising from the pelvis and apparently the size of a 14-weeks pregnancy. Vaginal examination

showed that this mass was a fibroid filling the pelvic cavity and projecting into the abdomen. The examining finger could not be passed above the tumour to identify the cervix, through which it was apparent the fibroid had been extruded. Transfusion was started and three pints of blood were given slowly. While the third pint was running, the patient, whose condition was now much improved, was taken to the theatre. The previous findings were confirmed, and after catheterization light obstetrical forceps (Wrigley pattern) were applied to the tumour. It was found that gentle traction did not reduce any appreciable descent; the pedicle could not be reached, and it was therefore necessary to remove the tumour by torsion or forcible removal. An episiotomy was performed and the forceps were only rotated. The tumour twisted so easily that it was obvious prision of the uterus could not be occurring, and with surprising ease the fibroid (see Fig.) separated at the base of its pedicle and was delivered. The uterus was small, no other fibroids were present, and there was practically no further haemorrhage and none from the pedicle. As no bleeding-point on the tumour was found it was obvious that the severe haemorrhages had been uterine in origin, and that there was no endometrial hyperplasia. The probable cause was due to its position and size the fibroid was elevating the uterus, stretching the uterine vascular pedicle, and thus producing a state of severe chronic congestion.

I have seen a similar case of severe anaemia due to constant bleeding from a normal uterus elevated into the abdomen by the pelvis filled with chronic faecal accumulations. In both cases cessation of bleeding occurred when the two different congesting causes were removed, and in both cases menstruation has since been normal.

Oxford.

JOHN STALLWORTHY, F.R.C.S.

The most effective and simple method of cleansing dairy equipment is by steam sterilization, but since any considerable extension of this method is impracticable at the present time, the Minister of Health (Circular 2319) has made new Regulations permitting the use of sodium hypochlorite solutions for this purpose. Approved solutions, a list of which is given in the circular, must have a total available chlorine content of between 9 and 12% w/w and not less than 0.7% of sodium chlorate to act as a "detector" should sodium hypochlorite solutions get into the milk. Copies of the Regulations can be obtained from the Stationery Office.

ANATOMY OF MORALE

The Structure of Morale. By J. T. MacCurdy, Sc.D., M.D. (Pp. 224. 8s. 6d.) Cambridge: The University Press. 1943.

Dr. MacCurdy is a well-known authority on psychopathology, and this book should have a wide appeal at the present time, especially as it is lucid and refreshingly free from technicalities. Based on the same sound biological foundations as Rivers and Trotter, it will also appeal to students of the more objective sciences, some of whom are a little apt to look askance at the psychological approach. At the outset he reminds us that the emotional, as distinct from the rational, side of our lives belongs to the mind that we share with animals. This naturally leads on to a study of the conditioning and de-conditioning of reactions (which he prefers to the label of "reflexes"), and thence to a searching analysis of the nature of fear in the light of such information. Not merely are we all liable to fear, we are also prone to be afraid of being afraid, and the conquering of fear produces exhilaration. The Germans in their exploitation of terror had not studied sufficiently the ways in which people may adapt themselves to actual or threatened danger. They themselves had the worst of all possible preparations in having been assured that no enemy aeroplane could penetrate their defences. Behaviour in the face of danger rests on previous emotional adaptations to "signals" just as with Pavlov's dogs. Thus evacuation has increased neurosis, while sticking at the job has tended to reduce it; what is really terrifying about any danger is inability to cope with it. Anticipation of ordeals may lead by training to proficiency in facing them. When there is a deadlock between a striving to do something and an inhibition which keeps it in check, fear arises. This section ends with a discussion of panic fear.

The second section deals with the basis of morale, starting from Wilfred Trotter's distinction between the union of cells to form a new unit, the body, and the integration of individuals to form a herd. In the former the co-operation is physiological, in the latter psychological. With man the "herd voice" is not merely a signal for instinctive responses, it has evolved into a body of traditional group experience. For man, he never so individual, can never escape his biological fate of being a herd animal. To this profound influence of tradition Dr. MacCurdy attributes the varying reactions of different nations under stress, attaching great importance to this as a factor in British morale. The German Empire and the kingdom of Italy, on the other hand, are but recent growths, and the effects of this on morale are skillfully dissected. He tactfully omits detailed discussion of French morale, and reserves his severest denunciation for that of Japan: "Humanity is not in their vocabulary . . . no cure for this cancer . . . except its extirpation." He concludes that the fundamental differentiation of democracy from the authoritarian States lies in its treatment of minorities.

Space prevents reference to the third section, on organization. Suffice it to say that this book is full of good things; it is interestingly written and, despite the gravity of the subject, entertaining.

ORTHOPAEDIC AND INDUSTRIAL SURGERY

The 1942 Year Book of Industrial and Orthopaedic Surgery. (Pp. 424. Illustrated. 19s.) Chicago: The Year Book Publishers.

This little volume gives a brief and pithy account of many interesting recent developments in orthopaedic and allied subjects. The editor is to be congratulated on his choice of material and the way in which it is presented. To the busy surgeon who finds it difficult to keep abreast with the large volume of literature which he should read to keep up to date such a book is invaluable. The subjects range from tuberculosis of bones and joints to all forms of fracture and dislocation, and bone tumours. A short concluding section deals with special problems of industrial medicine and surgery. The section on fractures of the neck of the femur, Volkmann's contracture, fractures of the patella, and fractures of the humerus are

of special interest. Many of the abstracts are supplemented by a brief editorial note, giving the editor's personal opinion.

There is one minor defect which is difficult to remedy in a book of this size. So far as is possible the illustrations correspond with the text, but in some instances the illustrations of one article overflow into succeeding pages and become divorced from their own text. A great deal of the value of the book lies in the excellence and multiplicity of its illustrations, so that they should not be cut down. The small size of the pages makes it difficult to balance the illustrations with the relevant texts.

VENEREAL DISEASES: A POPULAR BOOKLET

Venereal Disease in Britain. By Sydney M. Laird, M.D., Ch.B., F.R.F.P.S.G., D.P.H. (Pp. 80. 9d.) Harmondsworth: Penguin Books Ltd. 1943.

Many people have long been seeking information about venereal disease; now they have got it in *Venereal Disease in Britain*, by S. M. Laird. The publication of this little book written in popular language is more than welcome and cannot be considered a coincidence; the author knows his subject and proceeds to set out briefly the history of venereal disease, what it is, how prevalent it is, and how he thinks it should be dealt with. The facts are presented clearly and succinctly; the descriptions of gonorrhoea and syphilis could hardly be bettered, and the chapter entitled "The Tragedy of Venereal Diseases" is a picture by no means overdrawn. It calls to mind Brieux's *Damaged Goods*, and should serve to emphasize the axiom that early recourse to skilled aid is the way to avoid serious consequences which might otherwise wreck the lives of whole families.

It is when the author turns to the control of venereal disease by compulsory methods that he is on less sure ground. Is it certain that measures which have admittedly been successful in Sweden will be equally successful in Britain? Certainly there is much food for thought in the suggestions put forward; but those who are interested in the pros and cons of compulsory measures will do well to read in connexion with Dr. Laird's proposals the report of the British Mission¹ which visited Scandinavia in 1937 before coming to a definite conclusion. It seems very doubtful whether this country is yet ripe for full compulsion; legislation can hardly go ahead of public opinion.

This really excellent little Penguin Special deserves a very wide circulation. It is written for the man in the street, and all young men and young women will do well to ponder carefully over the lesson which it teaches; by so doing they may dispel their ignorance and save themselves and others much misery and many reproaches.

¹ Reports on Public Health and Medical Subjects, No. 83, 1938.

Notes on Books

The *Wilson Hospital in the Front Line* tells the story of the expansion of this Mitcham hospital (provided for the district by Sir Isaac Wilson) from a peacetime size of 72 beds to 123 beds as an "advanced base" hospital under the E.M.S., and of its work during the raids of 1940-1 for the injured of Mitcham. This locality had its full share of the horrors of that time, and the pamphlet (price 6d.) describes a typical night at the hospital during the height of the "blitz"—a story reflecting what organization and hard work efficiently and ungrudgingly performed can achieve under frequent air attack.

Preparations and Appliances

ROCKING DEVICE FOR ARTIFICIAL RESPIRATION

Dr. JOHN R. LAHIFF, a Major in the Home Guard, writes:

Since the publication of that admirable article by Surg. Lieut. G. H. Gibbens (*British Medical Journal*, 1942, 2, 751) I have been advocating in my lectures the use of Eve's rocking method

little time for invention when a drowning man is on deck." Surely we should not have to depend on improvisation when the possibility of the method being required is so universal and urgent, especially at sea and—who knows how soon?—"on the beaches."

The following is a description of a device which it is hoped might meet the situation. In the interests of brevity a diagram is included.

1. It will be seen that use is made of an ordinary stretcher.

2. The trestle arrangement is a fixture, and in no way interferes with the normal use of the stretcher as such.

3. The additional weight is only 4 lb., and the floor-clearance is not affected.

4. It can be opened and placed in working position in under 30 seconds. Thus the time-lag occasioned by improvisation is eliminated, as is also the confusion associated with the necessary coincidental initiation of artificial respiration by Schäfer's or Silvester's method.

5. It can take a person of any weight.

6. It will be seen that the height of the trestle is only 22 in., as compared with 32 to 34 in. as suggested by Gibbens. The purpose of this reduction in height is to ensure a uniform amplitude of "rock." The operator is instructed to hit the deck with the pole-ends at the completion of every rock. It is hoped that in this way an arbitrary amplitude will be avoided, and as a result a more regular rhythm rendered likely and a more uniform periodicity established. An initial sudden jerk of the "head" end downwards at 30 degrees would serve the same purpose as Gibbens's initial dip at 50 degrees.

7. The lower trestle also enables the operator to work the stretcher from the kneeling position. This is considered important, as back-bending would be unnecessary; it is far less tiring, and relays are therefore not required.

8. It is considered advisable that the operator should work at the head end of the stretcher, as he can then observe any signs of return to normal breathing and be ready to alter his rhythm.

9. The device is inexpensive, especially if provided in large numbers.

It is suggested that if all stretchers were to be fitted with such a device a great saving of life might be effected, especially at sea in wartime. They might usefully be included in the equipment of docks, canals, electric-power stations, bathing-beaches, swimming-pools, coal mines, etc.

I wish to record my gratitude to Major D. Walker, 71st Batta. (Ormskirk) H.G., both for his drawings and his help in providing a working model.

of artificial respiration. To most audiences the principle of the idea is readily acceptable and the little skill necessary to its application quickly acquired. Various suggestions for improvisation have appeared in the *Journal* and have emerged from demonstrations I have given. But, as Gibbens says, "there is

LONDON

SATURDAY JULY 10 1943

PROBLEMS OF HYPERTENSION

If any confirmation were needed of the frequency of hypertension it is provided by a recent study in the United States.¹ Defining hypertension as a blood pressure of 150 systolic and 100 diastolic or higher, the authors found that about one-third of the male population and over two-fifths of the female population at ages 40 and over had hypertension. So common a disease has naturally inspired a great deal of study, and visitors to America shortly before this war often came away with the impression that every clinic in the U.S.A. was working on the disease. So much literature has resulted from this activity that it has been impossible for the ordinary reader to keep pace with it, and many will be grateful to Prof. G. W. Pickering for making this the subject of his Oliver-Sharpey lectures, printed in this and our last issue. Pickering points out that a raised blood pressure, like a raised temperature, is a symptom which need not always have the same pathological basis. High blood pressure may be considered in relation to three main types of disorder. The first and most important is constituted by essential hypertension, chronic nephritis, and coarctation of the aorta. The second includes acute nephritis and the toxæmia of pregnancy, and the third is the rare form of hypertension due to excessive secretion of adrenaline by tumours of the adrenal medulla. Clinically, toxæmia of pregnancy resembles acute nephritis in respect to hypertension, albuminuria, and generalized oedema, and in both conditions there may be subsequent development of permanent vascular disease.² They differ from the first and major group of hypertensive cardiovascular disease in that the renal blood flow is not decreased, and, in acute nephritis at all events, the hypertension can be prevented by renal denervation.

The major facts which appear to have emerged in reference to the main group of hypertensive diseases are that the vasoconstriction is not neural in origin and that the renal blood flow is decreased. One of the chief stimuli to recent research has been the demonstration by Goldblatt that constriction of one or both renal arteries results in severe persistent hypertension with normal renal excretory efficiency as measured by urea clearance, a condition closely similar to essential hypertension in man. The steps by which it has been proved that essential hypertension is not due to structural changes in the arteries or to sympathetic overactivity are clearly shown in Pickering's lectures. The changes in the circulation are very different from those produced by neural vasoconstriction or by the adrenal and posterior pituitary hormones, in which the skin is depleted of blood. Pickering's calculations suggest that in essential hypertension there is a 40% decrease in the blood flow to the kidneys, a 60% increase to the muscles, and a 10% increase to other tissues such as the skin and the brain. It is also generally agreed that in the kidney vasoconstriction affects particularly the efferent glomerular arterioles. Very characteristic changes in renal function can be demonstrated by the searching method of the study of the clearance of inulin and diodrast. This demonstrates that the

tubular excretory mass or total function of the kidney is greatly reduced. The effective renal blood flow is also reduced, while the rate of glomerular filtration is much less reduced than the tubular function, so that the fraction of the renal blood flow filtered off in the glomeruli is increased.

It would seem appropriate to explain all these effects in terms of the Goldblatt experiment and its humoral consequences. When the blood flow to the kidney is restricted a substance renin is produced. Renin is a ferment, and it reacts with the alpha globulin of the plasma (hypertensinogen or renin-activator) to form a fairly stable substance, hypertensin or angiotonin, which produces the same type of rise in blood pressure as is found in essential hypertension.³ One might therefore expect that the primary disturbance in essential hypertension and chronic nephritis is a structural lesion in the kidney which produces a change in the blood supply to the glomeruli akin to the Goldblatt experiment, and it is indeed such a lesion of the afferent arterioles which Pickering postulates in his final hypothesis. The suggestion is made difficult of acceptance by the work of Castleman and Smithwick.⁴ These authors took biopsy specimens of kidney and muscle during the operation of sympathectomy for the treatment of high blood pressure. The average pressure in their hundred patients was 210/130, and the hypertension had been present for about six years. Nevertheless 28% of the biopsies showed no or insignificant vascular disease, and in an additional 25% there were only mild changes. It is clear that the end of the story is not yet told. Vascular changes in the kidney aggravate hypertension and produce a vicious circle, but it does not seem that the time has yet come to abandon the orthodox view that the hypertensive state precedes the renal vascular disease in many cases. We may have to look elsewhere for the primary disturbance of the renin-hypertensin mechanism that sets the fatal engine of destruction to work.

The clinician looks to research not for a sign but for a cure, and he will be anxious to know whether these discoveries have led to any advance in therapeutics. The answer unfortunately is: Not yet. The theoretical basis of the treatment of hypertension by sympathectomy has been undermined, though many would still defend the operation on its results in practice. It provides an opportunity to explore the adrenal glands and has revealed the unsuspected frequency of tumours. Seven of Castleman and Smithwick's patients had tumours of the adrenal glands, and two of them were pheochromocytomas of the medulla, which had presumably provoked the hypertension. The only immediate application of the Goldblatt experiment is the realization that hypertension may be produced by unilateral renal disease and may be relieved by unilateral nephrectomy. The disease must be of a type to produce atrophy and vascular sclerosis, and these conditions may be found in pyelonephritis and calculous nephritis. In hypertension of recent origin in the young subject it is always worth thinking of the possibility of unilateral renal disease and the relief of the hypertension by nephrectomy, though the chances of lasting improvement should not be rated too high. The possible medical applications of the renin-hypertensin mechanism seem more hopeful, though we are still in the land of surmise. Renin acts more powerfully in recently nephrectomized animals, and repeated doses of renin in intact animals rapidly diminish in effect. This and other evidence has led to the hypothesis of an angiotonin-inhibitor or hypertensinase which is secreted by the kidneys and to a lesser extent by the intestine. Extracts of kidney have therefore been prepared for the treatment of hypertension in experimental animals and man, but the

effects are often clouded by the presence of pyrogens and toxic principles which may themselves lower the pressure. Nevertheless, some of the results obtained are full of promise.⁵

EPIDEMIOLOGY OF DIPHTHERIA

The response to the campaign for immunization against diphtheria, despite the publicity given to it, has not been large enough to attain the desired result of eliminating diphtheria as a major cause of mortality. At a recent Press conference at the Ministry of Health the Chief Medical Officer stated that about half the child population had been immunized, and a drive to increase this proportion to at least three-quarters was to be made. In these circumstances the report by W. T. Russell⁶ has a topical interest. This paper gives an excellent statistical review of the trends of mortality and morbidity during the past 40 years and a chapter on immunization.

The mortality from diphtheria during this period has fallen by approximately 60% in England and Wales. Among the factors that may have been responsible for this reduction are: a possible change in the type of the disease; the improved social conditions of the last two decades, which may have increased the recuperative powers of those attacked; an increase in the proportion receiving hospital treatment at an earlier stage of the disease; changes in method of treatment. Hospital records support the last two suggestions. The case fatality rises rapidly as the length of the interval between onset and administration of antitoxin increases, and the curve of fatality reaches an asymptotic level at the fourth day, after which the progress of the disease is not influenced to any extent by antitoxin treatment. An example of changes in treatment is provided by the London hospitals. In 1916 the average dose of antitoxin was 16,607 units per patient, and in 1925 it was 26,335, while the corresponding average case fatality was 12.2 and 4.8. The decline in mortality has not been uniform for each age group but has fallen more rapidly for the pre-school ages of 0-5 than for the school ages. In the quinquennium 1906-10 the death rates at ages 0-5 was 163% and at ages 10-15 it was 15% of the rate at ages 5-10. In 1931-5 the death rate at ages 0-5 had dropped to 95% of the rate at ages 5-10, while the death rate at ages 10-15 had risen to 24%. An entirely different trend was observed in the U.S.A., where the rate at ages 1-5 rose from 207% of the rate at ages 5-10 in 1920-4 to 315% in 1935-8, while the rate at ages 10-15 fell from 26.4 to 22.0% of the rate at ages 5-10 during the same period. The fall in the birth rate and improvement in environmental conditions are the factors that were responsible for trend of the mortality in England and Wales. A study of the London rates shows that in the residential areas the rate at ages 0-5 as a percentage of the rate at ages 5-15 remained practically constant at 210 during the last 30 years, while in the densely populated areas the index fell from 637 during 1911-13 to 231 during 1937-8. As a result of the decreased birth rate the families in the overcrowded areas have become smaller; the children are not exposed to the same intensity of infection as formerly, and now tend to have a risk of infection that approximates to that of children in residential areas. The result is that in the poorer areas relatively more children contract the disease and die of it during school life than used to be the case. The opposite trend experienced in the United States was probably due to concentrating at first on immunizing the

school child, and the relative greater reduction of mortality at these ages indicates the efficacy of controlling the death rate from diphtheria by active immunization.

The annual case rates—based on the total population because the age of the patient is not notified to the Registrar-General—show a slightly rising trend during the past 30 years. The case rate fluctuated between 105 per 100,000 population to 186 during this period. The child population at ages 0-15 has declined from 32% of the total population in 1901 to 24% in 1931, and the slight rise in the notification rate means that there has been an increased incidence among children unless the incidence among adults has become greater. This may not be a real increase, because more attention is now paid to this disease and the number of doubtful cases has grown. Although a case is notified as diphtheria, no correction is made in the returns when a different diagnosis is arrived at in hospital. The diagnostic error in London was 15% in 1901-2, 23 in 1928-9, and at the North-Western Fever Hospital in 1931 it was nearly 50%. The incidence of morbidity in London follows the trend of mortality; the children aged 0-5 in the densely populated districts have a higher incidence than those in the residential areas; but whereas the children aged 5-10 in the residential areas had a rate in excess of those in the densely populated areas during the first part of this century, the position was reversed at the end of the period. A similar change in the adult notification rate in London was noted. In the first part of the period the rate for adults was greater in the residential districts, but at the end of the period the rate was lower than in the overcrowded boroughs. No national statistics of age incidence are available, but the reports of the local M.O.H. suggest that variations exist between the age distributions of different areas. During 1936-7 one-third of the cases notified in London were aged 0-5, while in Manchester one-fifth of the cases were in this age group, although the children in the group formed 7.52% of the population in Manchester, compared with 6.76 in London.

Russell reviewed trends of diphtheria in New York and Toronto, where inoculation has been intensively practised. He concluded that there is strong evidence that immunization has lowered the mortality and morbidity rates in both cities. Although the incidence had been declining before immunization was introduced, the statistical evidence of diphtheria in both cities is significantly better than would have been expected from the trend of either mortality or morbidity in the pre-immunization period. In the pre-immunization period an epidemic occurred at intervals of six years in New York and four years in Toronto, and therefore epidemics should have appeared in both cities between 1930 and 1940 but did not. The proportion of children immunized in the county borough of England is in sharp contrast to New York City and Toronto: there were two towns, Hastings and Hull, where fewer than 50 per 1,000 had been immunized during 1940, and only one town, Lincoln, where half the children had been immunized. A comparison of the experience of the large county boroughs with a population of 150,000 or more shows some interesting contrasts. Hull and Liverpool had the highest death rates, 72.7 and 60.5 per 100,000 of the population aged 0-15, and the highest notification rates 278 and 253, and the lowest proportion of children immunized, 47 and 57 per 1,000 respectively. Bolton and Newcastle with large immunization rates of 346 and 306 had death rates of only 17.9 and 19.7. A negative correlation was found for immunization and both mortality and morbidity, though the former was not statistically significant.

The discovery and classification of three types of diphtheria bacilli—mitis, intermedius, and gravis—has enlarged

⁵ Page, I. H., and Corcoran, A. C., *Advances in Internal Medicine*, 1942, 1, 183.

⁶ *The Epidemiology of Diphtheria during the last Forty Years*, by W. T. Russell, D.Sc. Med. Res. Cncl. Sp. Rep. Ser. No. 247. H.M. Stationery Office. (1s.)

he scope of diphtheria statistics. The last two are generally said to be the severe forms of the disease and have a high fatality, while infections of the first type are milder. From the data available it appears that gravis is now the prevailing type, but there is not enough statistical evidence to show that this type is always accompanied by a high mortality. There is evidence that the type of infection varies within a district. The predominant form in Edinburgh during 1936 was intermedius with 54.4%, and gravis formed only 28.1% of the infections, but as a result of a continuous rise in the proportion of gravis the percentages were 83.3 for gravis and 10.8 for intermedius in 1939. In 1937 the most frequent type in Liverpool was mitis, 41.1%. This proportion fell to 11.1 by 1941, while during the same period gravis rose from 34.2 to 71.1%. The experience of Southampton showed that the types were in constant proportions during the years 1936-40, with about two-thirds of infection due to mitis. The changes in the type incidence may be related to the proportion of immunized children, but the data are not large enough to make this more than a suggestion.

ACTION OF DIGITALIS

For many years it was believed that digitalis influenced the heart mainly by a vagal action which slowed the rate. This belief arose from the fact that digitalis was regarded as a specific in the treatment of auricular fibrillation; and it is only after some 30 years of clinical and laboratory study that attention is now more specifically focused upon the action of digitalis on the heart muscle. Thus Gold and his co-workers¹ showed that the slowing brought about by small doses of digitalis in man was abolished by large doses of atropine. This vagal slowing could be attributed to a reflex following the improvement in the myocardial compensation. After larger doses of digitalis, however, atropine no longer increased the cardiac rate, so that the ventricular slowing must have been due to an extra-vagal action of digitalis. The practical importance of these considerations is expressed in the fact that arrhythmias must no longer be regarded as the primary indication for digitalis therapy, but rather cardiac decompensation. There is also a tendency nowadays to turn to the use of the pure alkaloids separated from the crude digitalis leaf; and it must be admitted that the methods of standardization of the crude leaf were not always an absolute reflection of the therapeutic requirements. Rose and his associates² found that digoxin was very satisfactory when given orally to some 88 patients, of whom 55 were under constant supervision in hospital. For rapid digitalization they recommend an initial dose of 1.5 mg., followed by 0.75 mg. six-hourly until the desired effect has been achieved. These doses may be increased or decreased by 0.25 mg. to suit the individual patient, and the average therapeutic and toxic doses by this method were 3.75 and 6 mg. respectively. For digitalization with single doses daily they recommend 1 to 1.5 mg., and for maintenance somewhat less than a third of that required for full digitalization. The toxic manifestations with digoxin were like those of the crude leaf, but of brief duration. Though intravenous therapy (1.5 to 2.5 mg.) was followed by an effective response, usually within 15 minutes, there were 2 fatalities in the series of 13 patients; these patients were in any event bad risks, and it is not certain that death was in fact immediately due to the digoxin, but the limitations and dangers implied are self-evident. On the other hand Tandowsky³ has studied the glycoside lanatoside C (from *Dig. lanata*)

on some 40 patients, comparing the effect of 16 gr. *Dig. purpurea* orally with a single dose of 1.6 mg. lanatoside C intravenously. The maximum alteration of the S-T segment in the E.C.G. was seen within 2 to 3 hours, which was 11 to 12 hours sooner than with *Dig. purpurea*. There were no fatalities; toxic effects were mild and transient, and on these grounds Tandowsky recommends the drug especially where quick action is desirable or gastrointestinal symptoms are troublesome. However, it is reasonable to expect further clinical trials before these drugs displace entirely ouabain, the strophanthin derivative, in parenteral therapy, and in general it can be said that claims for a particular glycoside based on the toxicity are deceptive, as the toxic manifestations are mainly extensions of the therapeutic effect.

TRANSMISSION OF KALA-AZAR BY THE SANDFLY

Few tropical diseases in the course of their investigation have more puzzled and at times more surprised the research worker than has kala-azar. It was first thought to be a form of chronic malaria, and from this arose the classical conception of "malarial cachexia." Discovery of the Leishman-Donovan body brought to a sudden end the controversy as to whether or not kala-azar was malaria or some other condition. No sooner had workers begun to speculate on the nature of this quite new and strange form of parasite when Rogers found that Leishman-Donovan bodies developed into flagellates of the well-known herpetomonad type when kept *in vitro* under certain conditions. The next mystery was the manner in which this parasite, included in the visceral cells, could be transmitted. The most likely view was that it was carried by an insect host, a possibility made more feasible by the discovery that the parasite did at times occur in the peripheral blood, though in small numbers. The most promising of possible vectors appeared to be the bed-bug, but after much work it became clear that this pest must be exculpated. Experiments were made on lice, *Triatoma*, *Ankylostoma*, and other possible hosts. Finally Knowles, Napier, and Smith, working on the Ancillary Kala-azar Inquiry at Calcutta, recorded that in the gut of sandflies fed on kala-azar cases flagellates could be observed which were indistinguishable from the flagellate form of the Leishman-Donovan body—an observation soon proved to be true. Investigation of this stage in the life history of the parasite was further carried out by feeding experiments by the Kala-azar Commission in Assam. Shortt, Barraud, and Craighead found that in a proportion of fed flies the buccal cavity was so heavily infected with flagellates that a bite could scarcely fail to inject the organism when the flies next fed. Once more, however, the smooth course of investigation was interrupted, for the laborious efforts of Shortt, Craighead, and Smith to infect human volunteers by the bites of sandflies fed on kala-azar cases were uniformly unsuccessful. In one series alone in this work over a quarter of a million sandflies were reared and nearly one hundred thousand fed. It is with especial interest, therefore, that we can now record the successful transmission of the kala-azar parasite through the bite of the sandfly. This is the work of Swaminath, Shortt, and Anderson,¹ who have followed the technique described by Smith, Halder, and Ahmed in 1940: infected sandflies were kept alive by feeding on vegetable juices until ready to infect. Five human volunteers were utilized and all five developed infection. Thus at the end of some twenty years of almost continuous active research has the final proof been given of the sandfly transmission of this dread and widespread tropical disease.

EVACUATION: A BRIGHTER PICTURE

We have had so many dismal tales from the reception areas that it is all the more refreshing to get a report from one of them which gives, not indeed a rosy picture, but one less dun-coloured than most. The area is Westmorland, which received during four evacuation periods 11,600 children, chiefly from Newcastle and South Shields, but some also from the other side of England, at Barrow. In a booklet issued by the county council Dr. J. F. Dow, the county medical officer, and Miss M. A. Brown, a psychiatric social worker, describe Westmorland's experience. Here as elsewhere bed-wetting among the evacuees was a major difficulty. It is stated that the enuretics were divisible into four groups: those who had a short spell of enuresis as a response to a new and difficult situation; those who found difficulty after their home training, or lack of it, in adjusting themselves to a higher standard of cleanliness; those who were highly strung and nervous; and those whose enuresis had some physical background. Some of the chronic cases cleared up completely on the children being removed from the homes where they were billeted and placed in hostels. Others who were thought to have improved broke down again when faced with difficulties in school or in their billet. Purely medical treatment by drugs when no physical cause was found was of little use, and various experiments with recommended remedies completely failed. Next to this group the largest number of "referred" children were those showing behaviour problems, but these were mostly superficial, and the opinion is expressed that juvenile delinquency has been exaggerated. An analysis of the cases of difficulty showed that the fault was more often in the parents than in the children themselves, and sometimes it lay to a certain extent in their hostesses. The evacuated children in Westmorland gained in every way physically, and proved wonderfully free from infectious diseases. The problem of scabies was larger than had been expected, but the use of benzyl benzoate emulsion reduced it to small proportions. On the whole a tribute is paid to the children, who showed great powers of adaptability. The chief disappointment was the heavy drift back during the first few weeks immediately after each of the evacuations.

THE WELLCOME MUSEUMS

Frequent inquiries are being received, from this country and abroad, with regard to the Wellcome Museum of Medical Science and the Wellcome Historical Medical Museum. They are, and will continue to be, housed in the Wellcome Research Institution, 183-193, Euston Road, N.W.1. The Wellcome Research Institution building suffered considerable damage by enemy action, but its structure was unharmed and the museums can quickly be put into shape again as soon as labour and materials become available after the war. Though some of the objects in the Wellcome Historical Medical Museum were damaged, it has been possible to replace or repair most of them. Fortunately the specimens and other valuable material in the Wellcome Museum of Medical Science remained comparatively intact. Both museums are now under the directorship of Dr. S. H. Daukes. A comprehensive scheme for the Wellcome Historical Medical Museum has been prepared and will be brought to completion as soon as possible after the end of hostilities. The Wellcome Medical Library, comprising over 150,000 volumes, will also be in the same building, and suitable accommodation will be provided for research workers so that both the library and collections may be readily available. The Wellcome

Museum of Medical Science—which in the past has been much used by teachers, students, and those engaged in postgraduate studies—will be re-established in its entirety at the end of the war with the utmost speed. The Lecture Hall will be fully re-equipped, including film projection apparatus, and will then be available for scientific lectures and meetings.

THE WAR AND THE PRESS

So gradual have been some of the changes brought about by total war that many otherwise observant people would be astonished if they held in one hand a copy of their favourite newspaper or review of to-day's date, and in the other a copy published four summers ago. Reduction in bulk is the most striking effect of the shortage of paper, but every periodical has adopted other means for economizing space, such as the use of smaller print and narrower margins, and all who can do so have cut down circulation. Hard is the lot of this *Journal*, with an obligatory circulation of 42,500 copies a week and an inflexible Parliamentary Controller; the ration simply will not suffice. In a recent speech on "The Press and the Nation in Wartime" Lord Colonel J. J. Astor, chairman of the Times Publishing Company, dwelt on the important part played by the Press in our democratic institutions in peace, and even more in war. Besides reporting events it has the function of explaining Government policies and schemes, and also criticizing and showing up Government schemes when they are not operating fairly or as intended. This is the good of scientific and professional organs no less than reputable daily and weekly newspapers. So, too, in the matter of censorship: in wartime, as Colonel Astor said, there has to be a censorship, but ours in this country is voluntary. Guiding lines are given, certainly; some form of information obviously helps the enemy. When in doubt an editor naturally refers to the Censor, and where men's lives are involved the final decision must rest with the Service authorities. At times the Censor has seemed to the Press to go rather far, but Colonel Astor reminded his hearers that censorship is not a normal occupation, and was inevitable that at the beginning of the war there should have been mistakes and unnecessary delays—not all of them the fault of the Censor. For our part we have no quarrel with that section of the Press and Censorship Bureau with which we make contact on the score either of delay or of obstruction; submitting proofs is just one of the trials of journalism in wartime. With regard to the drastic rationing of paper, Colonel Astor said (and we agree with him) that if a newspaper is to carry out its function—to give news and relevant comment, to give Parliamentary debates, official statements and lists of honours and awards, to encourage salvage drives, etc., and to retain its features in however attenuated a form—then the Press has made the maximum economies and has reached the minimum consumption of paper necessary to perform these functions.

It is hoped that doctors who send in notifications of change of address will understand that delay in putting these into effect is inevitable by reason of the exceptional conditions under which the depleted staff at B.M.A. Headquarters is working. As many as 900 changes of address, and in the rank of serving members, may be notified in a week. Each of these changes has to be stamped on to a new plate for the *Journal* wrapper. The work is heavier than in peacetime; the staff is fewer. Members are therefore asked to be forbearing if what seems to them a very small alteration is not made as quickly as they might expect.

SOME PROBLEMS OF REHABILITATION

BY

HAROLD BALME, O.B.E., M.D., F.R.C.S.

Emergency Medical Service

Rehabilitation is the popular term of the moment, as freely discussed in non-medical as in medical circles. As is usually the case with new forms of therapy, there is for the time being a violent swing of the pendulum, and rehabilitation threatens to displace the old-time tonic as a convalescent cure for one and all. This may possibly be followed by an equally violent swing in the opposite direction. But there is little doubt that rehabilitation has come to stay, and will form an integral part of the health services of the future. It is therefore of the utmost importance that its problems should be carefully studied and understood by the profession, and the fullest advantage taken of the present opportunity, created by war conditions, to test out experimental methods and lay the foundations of a sound and scientific scheme.

Nothing would be more unfortunate than for rehabilitation to be divorced from medical or surgical control and established as a new health cult. But that is exactly what may happen unless the profession takes the matter seriously and exercises a guiding and controlling hand; for rehabilitation is a subject which goes far wide of medicine and surgery. Already it is interesting the Ministries of Labour and of Fuel as a means of expediting the recovery of workmen after serious illness or injury and ensuring a more rapid return to employment. It is interesting all who are concerned with physical culture and with the maintenance of general fitness. And not only does it form the central theme of the Tomlinson report but it is written deep in every scheme of post-war sociological planning. There is a real risk of rehabilitation becoming an entity in itself, with so-called rehabilitation centres opened up all over the country without any adequate medical supervision, and a fruitful and most promising form of therapy thus led away along unscientific lines. That will not happen if the medical profession takes firm control from the outset, but to assume such control it is necessary to have a clear view of the problems involved and of the methods by which they may best be solved. It is the purpose of this article to marshal the chief facts connected with rehabilitation, and to attempt to suggest the lines along which healthy development may follow.

In the first place, what do we mean exactly by rehabilitation? It is an unfortunate and clumsy term, and one which is already being used with a variety of different meanings, but from a strictly medical and surgical aspect it can perhaps best be defined as the method by which physiological function is fully restored after its temporary loss from injury or illness. This applies to every form of debilitating disease, accident, or surgical operation, and equally in the physical and the psychological spheres, and no rehabilitation is complete unless it pays due regard to both.

At this point we are met with the objection, already articulated in some quarters, that the physician's task is to cure disease, and that if we will stick to our job Nature will do the rest. We seem to have met that objection before, but it really will not bear a moment's consideration, for the whole purpose of the physician and surgeon, when it comes to questions of ill-health and injury, is to supply what Nature lacks. Every surgical operation, every modern therapeutic agent, every use which we make of serology and roentgenology and physical medicine, bears witness to our conviction that Nature, unaided, will not by any means necessarily perfect her cures. This is as true of the restoration of function as it is of the overcoming of infection, the setting of a fracture, or the removal of a malignant growth. It is therefore incumbent upon us to make a careful study of the factors which prejudice full and speedy return to vigorous health, and the methods by which those obstacles can best be met and overcome.

Let us consider, in the first place, the facts which we require to know as a preliminary to formulating a sound and scientific scheme of rehabilitation. We shall then be in a position to discuss such important questions as the organization of a rehabilitation team, the training of staff, the grading of patients,

the provision of the essential facilities, the preparation of handbooks, the relationship of in-patient, out-patient, and post-hospital rehabilitation, and the resettlement of the rehabilitated patient in some form of useful employment.

Problems for Research

A vast amount of time and thought is constantly being expended on the diagnosis and treatment of disease and injury, but surprisingly little attention has ever been paid to the equally important question of the restoration of function. There are innumerable points upon which more research and statistical study is needed before a sound programme of rehabilitation can be drawn up. Here are a few of them:

1. The effect of trauma on every type of soft tissue—fascia, muscle, tendon, serous and synovial membrane, etc.—demands careful study, and we need to know far more accurately than we do at present at what stage, and to what extent, restricted movement is beneficial or harmful, both to healing of the injured part and to the rapid and complete restoration of function. For lack of this exact knowledge many of our rehabilitation methods are of the nature of trial and error—hence the contrary views of those who advocate and those who oppose early remedial exercise. It should not, however, be difficult, by means of controlled experiment carried out on a sufficient number of cases, to establish definite criteria by which to judge of the methods suited to each class of disability and to each stage of recovery.

2. The relationship of pain to immobility is by no means clearly defined; still less do we know of the conditions under which it is wise to abolish pain and promote mobility in diseased or traumatized tissue. It is commonly claimed that pain is Nature's call of alarm, demanding rest and immobilization for the injured part; but that is by no means the whole of the story. We are all familiar with the type of pain produced by stretched ligaments and adherent soft tissues in which mobilization, and not immobilization, will alone cure both the stiffness and the pain. We are familiar, too, with the so-called "vicious circle of pain," as illustrated by certain injuries in the neighbourhood of joints, the trauma producing effusion which causes pain, and the resultant pain leading to sympathetic disturbance and vasodilatation, and hence to more effusion. In such conditions the abolition of pain by deep novocain injection, as advocated by Leriche, or by intensive freezing with ethyl chloride, certainly hastens the restoration of function in a large number of cases. The same may well be true of other analogous conditions in which pain is associated with immobility. In this connexion an interesting suggestion has been made by a recent colleague of mine, Mr. J. M. Fitton, that the frequency of persistent pain after severe spinal injuries—a frequency much more pronounced than after equally severe injuries in other parts of the body—may not be merely a "litigation neurosis," as so commonly alleged, but may be due to the fibrosis and adhesion of soft tissues, and that where manipulation fails to effect a cure it would be worth while to try the effect of mobilizing the parts by open operation, followed by a course of remedial exercises. It is a suggestion well worth putting to the test.

3. It is now generally accepted that prolonged immobilization is to be deprecated in the treatment of fractures, owing to its tendency to produce muscle-wasting, stiff and painful joints, and decalcification of bone. What is not so clear, however, is the best time for starting muscular activity. One school of orthopaedic thought states positively that any movement prior to bony union is harmful, and that, provided a well-fitting skin-tight plaster is applied, bony union within reasonable time is certain, after which movement should be started; whereas, according to these authorities, a padded plaster and early movement involve a serious risk of non-union. This view is countered by others who claim that, provided the fracture is in good alignment and controlled by a properly applied padded plaster, changed at intervals, muscular drill within the plaster combined with regular exercise of the more distal joints (e.g., the hip and toes in the case of fracture of the tibia) not only never leads to non-union but actually expedites the date at which consolidation occurs. This is a matter which can only be settled by experiment over a long series of cases, but it is obvious that if the latter contention is the correct one, and the adoption of such measures reduces the period of inactivity of all fracture cases by a week or a fortnight, the resultant gain all over the country, as expressed in man-day power, would be a great economic asset.

4. Too little is yet known as to the factors which hinder return to full use of a joint subjected to open operation, such as a knee-joint after meniscectomy. Most orthopaedic surgeons have to admit to a small minority of cases in which complete recovery is delayed by pain, by lack of full flexion, or by recurrent effusion. How far is this due to inadequate haemostasis at the time of operation; to particular methods of technique; to low-grade sepsis or local irritation; to too early or to too late movement; to excessive or to inadequate quadriceps drill; to too drastic or to too premature attempts at flexion; or to the use of such resistance exercises as those

provided by weights and pulleys? Far more evidence is needed than is yet available on all these points before we can answer any of these questions, but such evidence is essential if the right methods of rehabilitation are to be chosen for such cases, and—what is perhaps even more important—if patients on whom remedial exercises will have to be slowed up are to be recognized early.

5. The optimum range of movement for every type of disorder, adapted to the stage of recovery, needs to be carefully worked out and formulated. Too often this is left entirely to masseuses or physical instructors, with no medical supervision and no means of checking whether the exercises given are suited to the particular joints or muscles affected, or are too strenuous or not sufficiently active.

6. The remedial exercises in current use have mostly been designed for traumatic cases. But rehabilitation is required for every form of debilitating illness or disorder, not merely for those resulting from accident. Similar care is therefore needed in working out progressive courses of rehabilitation for every variety of medical and surgical complaint. Special exercises are required for thoracic patients, both to promote the activity of the thoracic muscles and to assist good breathing; for post-operative abdominal and hernia cases; to say nothing of the special needs of head injuries, neurotic and psychotic patients, tuberculous patients, infirm children, etc. There is a great deal of work to be done for each of these groups.

7. The particular apparatus to be employed in the work of rehabilitation, especially the place to be allotted to the use of weights and pulleys; the association of occupational therapy, and its application to the various forms of remedial exercise; the choice of suitable indoor and outdoor recreations and handicrafts, adapted to each type of disability; the place of fatigue in the exercising of traumatized or wasted muscles—all these are examples of other matters requiring careful observation and statistical study.

War conditions have given emergency and Service hospitals a unique opportunity of working out rehabilitation experiments, owing to the fact that in certain of them it is possible to keep patients from the day of injury until they are fit to return to full duty. If each of these centres would concentrate on one of the above problems for research valuable material would be secured on which to base future programmes.

The Grading of Patients

If remedial exercises and other forms of rehabilitation therapy are to be adapted to the stage of recovery it is essential that some form of grading should be introduced and patients regularly allotted to the particular group to which they belong at any particular time. In one emergency hospital in the North of England to which a large rehabilitation department is attached such a system has been in operation for the past year and has proved of great benefit, both to the patients and to the staff. At this particular hospital five grades are recognized, the programme for each of which is as follows:

Grade 1: Bed patients.—Muscular drill. Faradism and massage where indicated. Assisted exercises. Light occupational therapy, mainly of a diversionary character.

Grade 2: Patients just beginning to get up.—Light remedial exercises. Mild team exercises, of short duration, for patients suffering from similar disabilities and in the same grade. Some remedial occupational therapy, where applicable.

Grade 3.—Stronger exercises, with introduction of some mild form of resistance (e.g., weights and pulleys). Cycling for patients with weakened thigh and leg muscles. Remedial occupational therapy. Organized games, carefully chosen in relation to the particular muscles requiring strengthening or the joints needing to be mobilized.

Grade 4.—Increased resistance introduced into all forms of exercise, both individual and team. Longer periods, including some marching. Heavier occupational therapy (e.g., wood-sawing, digging, carpentry, loom work against resistance springs). More strenuous games.

Grade 5.—A hardening course, including cross-country running, jumping, heavy occupational therapy (e.g., wood-splitting, stone-shifting, etc.), and various team games.

One of the chief values attaching to such a system of grading is that every patient is kept strictly under medical supervision, only the doctor having authority to "up-grade" a patient, or to "de-grade" anyone who is reacting unfavourably to the type of course assigned to his particular group.

Organization of a Rehabilitation Team

A full rehabilitation team comprises four distinct groups, which may be briefly described as prescribers, medical supervisors, co-ordinating officers, and technicians. In a small

hospital, where patients undergoing rehabilitation are but few these four groups would be reduced to three or even two; but in larger centres all four will be needed, and the closer the co-operation between them the more effective will be their work.

The group entitled "prescribers" will of course consist of the physicians and surgeons actually in charge of the patients, whose duty it is to signify when rehabilitation should start. In some instances they will prefer to supervise this treatment themselves but in most cases it will be found far better for the work of medical supervision to be delegated to one or more members of the whole-time medical staff, whose duty it will be to keep an eye on the type of exercise, etc., given to each grade, to assist in the training of the technical staff, to supervise the keeping of accurate progress records and individual graphs, and to examine every patient whose improvement is held up by pain or other unfavourable reactions. Such a supervisor will usually be charged with the responsibility of changing patients' grades, called for, unless the original prescriber prefers to do it himself.

The task of the "co-ordinating officer" is to see that in various forms of remedial exercise, occupational therapy, recreational therapy laid down for each grade are correctly given; to arrange the programme of each patient; to note new prescriptions ordered by the prescriber or medical supervisor, and see that they are put into force; and, generally speaking, to act as liaison officer between the masseuses, physiotherapy training instructors, and occupational therapists, welding them into one unified team of rehabilitation workers.

The practice which has been adopted in some hospitals of holding weekly meetings of the whole team, doctors included, at each of which some particular disability is fully discussed, cannot be too highly praised. At such meetings a preliminary talk is usually given on the anatomy of the particular region under consideration and the diseases or injuries likely to interfere with its function; x-ray plates and actual clinical cases demonstrated; and a free discussion follows as to the form of physiotherapy, remedial exercises, games, and occupational therapy suitable at each stage of progress.

Training of the Rehabilitation Staff

This is another problem demanding careful consideration and planning. Rehabilitation should not be regarded as a combination of therapy to which masseuses, electrotherapists, physiotherapy experts, and occupational therapists each make their own individual and separate contributions. It is essentially a single process, and should be so conceived. Ideally, therefore, the staff should be trained together in an institution attached to a large rehabilitation centre, and this is probably what will happen after the war. For the present this hardly seems practicable, and the various schools of physiotherapy, occupational therapy, and physical culture are therefore attempting to organize courses in active remedial therapy in addition to the training which they have previously been offering. This is certainly a move in the right direction, but it still leaves much to be desired, as each section continues to receive training in a separate unit instead of as part of a single rehabilitation team. Possibly the only way to counteract this tendency during the war will be by the establishment of special postgraduate clinics at the larger and better-equipped rehabilitation centres, where masseuses, physical training instructors, and occupational therapists will all be eligible to attend, and which will qualify for appointment as recognized rehabilitation technicians.

A very urgent need in connexion with the question of training is the provision of suitable textbooks. A comprehensive volume, describing in detail the various forms of remedial exercise, organized games, and occupational therapy in connexion with rehabilitation, has already been written and should be published in the early autumn; and a valuable handbook of the special remedial exercises suited to each type of disability and to each grade of recovery is now in preparation.

Provision of Essential Facilities

In considering the problem of how to secure the necessary accommodation, apparatus, and trained staff for the carrying out of rehabilitation it must be remembered that, although war has provided a unique opportunity of undertaking the process of rehabilitation at a single centre, as at certain

and emergency hospitals, this is but a temporary stroke of fortune. Normally, rehabilitation will more often be carried out in three stages, though this must never be allowed to interfere with the continuity of treatment. These stages are:

(a) The period of in-patient treatment, during which the type of rehabilitation therapy described above as Grades 1 and 2 would usually be given.

(b) Out-patient treatment following on discharge from the wards.—Where practicable—e.g., where patients are able to attend daily, and to remain not less than half a day for the purpose of remedial exercises, organized remedial games, and occupational therapy—this would ensure the continuity of rehabilitation in the case of patients who can no longer be retained in the wards and for whom suitable accommodation cannot readily be secured in rehabilitation centres. Such cases might be carried through Grades 2 and 3 without involving the hospital in the necessity for providing very elaborate accommodation or equipment.

(c) Treatment in a special rehabilitation centre.—Such centres will doubtless be set up after the war—in some cases even during the war—in suitable country surroundings, easily accessible from the towns from which patients are received, and equipped with gymnasium, playing fields, occupational therapy workshops, swimming pool, and other requirements for full rehabilitation therapy at all grades. Such centres should of course be intimately connected with the hospital or hospitals from which patients are received, the patients remaining under constant medical supervision, preferably carried out by the supervisor who initiated their rehabilitation treatment in the hospital at which they were first treated.

It will be seen that under such a scheme as the above, ordinary hospitals which do not carry patients beyond Grade 3 will not need to provide extensive playing fields or occupational workshops. What they will need, however, and what they should set about providing at once, are:

(a) A trained staff, keenly interested in active remedial therapy (as opposed to massage, passive movements, radiant heat, etc.) and thoroughly versed in suitable and progressive courses of remedial exercises, games, and occupational therapy.

(b) At least one or two masseuses, and, where possible, a physical training instructor and occupational therapist, trained in remedial work, whose whole time is devoted to active rehabilitation.

(c) A commodious room adapted for use as a gymnasium, remedial exercises, and indoor remedial games, and fitted up with simple apparatus such as weight-and-pulley circuits, wall bars, pronation and supination machine, wrist rollers, ropes, plinths, and benches.

(d) Facilities for providing simple occupational therapy, especially such as is useful for mobilizing stiff fingers, such as basket-work, netting, cane-work, and simple embroidery.

(e) A suitable place within or adjoining the hospital grounds for such organized outdoor games as medicine ball, netball, etc.

It must be remembered that, to be thoroughly successful, rehabilitation should occupy best part of a patient's day. It is not enough to arrange for attendance at a course of exercises for a brief period three or four times a week, or even daily, if the rest of the day is left unoccupied. One of the greatest values of rehabilitation is on the psychological side, as the patient's mind gets directed towards his return to full health and he is encouraged to co-operate in the process. For that reason his day should be filled up as fully as possible, not merely with courses of team exercises—his muscles will soon tire if such exercises are continued beyond a half-hour or forty-minute period—but also with other forms of exercise, games, and remedial handicrafts. Very few hospitals yet have the accommodation or staff to provide such facilities for a whole day for any one patient; but all should aim at a full half-day programme for each patient, some attending for morning sessions and the remainder in the afternoon or early evening.

Resettlement in Industry

The task of resettling convalescent patients in employment is obviously not one which devolves primarily on the medical profession, but if the work of rehabilitation is to be carried to its logical and desirable conclusion the collaboration of hospital authorities and of medical supervisors will be essential. This will take the form of advising when a particular patient is fit to return to duty; of indicating whether he can return to his former employment or should be given lighter duties, or, alternatively, whether he should be trained for some different and more suitable vocation; of establishing relations with

industrial medical officers in the carrying out of such recommendations; and, where possible, of reviewing the case after return to full work, either by means of medical reports or by actual examination of the patient himself.

In carrying out this essential terminal phase of rehabilitation the assistance of specially trained social workers, attached to hospitals and rehabilitation centres, is of the utmost importance. It is they who should keep track of each patient's attendance at the rehabilitation department, looking up any who are persistently absent. They should receive the medical officer's recommendations as to patients' return to duty. They should keep in intimate touch with employers and arrange for the re-engagement of those fit to start work. They should make contact with the Labour Exchange authorities in relation to cases that require to be trained in one of the vocational training centres established by the Ministry of Labour. Finally, they should be qualified to assist the patient in the intricate problems arising out of the present laws governing workmen's compensation, encouraging him to attempt light duties in spite of the reduction in disability allowance, while at the same time keeping industrial medical officers informed of the condition of each worker returning to work in factory or mine after illness or injury.

Summary

Rehabilitation is defined as the method by which physiological and psychological function are fully restored after their temporary loss from injury or illness.

An organized system of rehabilitation should be regarded as an integral part of the treatment of all debilitating diseases and injuries.

It is essential that it should not be divorced from medical and surgical control, but such dissociation is liable to occur unless its problems are closely studied by the profession and a sound scheme is adopted by all hospital authorities.

As a guide to the formulation of such a scheme a list is suggested of subjects on which further research and statistical study are required.

A system by which patients undergoing rehabilitation are graded according to their stage of recovery is recommended.

The various groups which should constitute a rehabilitation team, and the responsibility devolving on each, are outlined.

The training of the rehabilitation staff, and the provision of the facilities required by hospitals and by special rehabilitation centres, are discussed.

The contribution of rehabilitation medical officers and of hospital social workers towards the resettlement of patients in industry is indicated.

TEACHING OF ANATOMY

MR. CONNOR BANTRY WHITE of Westminster Hospital Medical School writes: The following extract, taken from an old anatomy book in my possession, shows that the concern felt by teachers of anatomy is by no means recent, and, I think, aptly summarizes the opinions put forward by your correspondents: "The study of Anatomy, as it leads to the knowledge of nature and the art of healing, needs not many tedious descriptions nor minute dissections; what is most worth knowing is soonest learned, and least the subject of disputes; while dividing and describing the parts, more than the knowledge of their uses requires, perplexes the learner and makes the science dry and difficult." This is the first sentence of the preface to the ninth edition of *The Anatomy of the Human Body*, by W. Cheselden, Surgeon to His Majesty's Royal Hospital at Chelsea. His book was printed in London in 1768.

After several refusals to go to the U.S.A., von Helmholtz was persuaded by the German Government to represent German science at the Electrical Congress held in Chicago in 1893. In a letter to Dr. Knapp, announcing the date of his arrival in New York, von Helmholtz, who was then 71, wrote: "I am convinced that America represents the future of civilized humanity and that it includes a vast number of interesting people, while in Europe we see only the approach of chaos or of a world dominated by Russia." Dr. Knapp, who was the recipient of this letter, was the founder of the *Archives of Ophthalmology* and the father of the present chief editor of that journal. ("Purkyne, a Pioneer in Ophthalmoscopy," William Thau. *Arch. Ophthalm.*, Chicago, 1942, 27, 299.)

HAEMOLYTIC TRANSFUSION REACTIONS: THE Rh FACTOR

A memorandum on "The Danger of Haemolytic Transfusion Reactions due to Immunization of the Recipient to the Rh Factor," prepared by the Blood Transfusion Committee of the Medical Research Council, has been circulated by the Ministry of Health to hospitals of the Emergency Medical Service and to all the Maternity Services.

Danger of Reactions due to Immunization to Rh Agglutinin

It is now known that the red blood cells of the majority of human beings contain a hitherto unrecognized agglutinin Rh. The term Rh is used because a similar agglutinin is present in the red blood cells of rhesus monkeys. Approximately 85% of bloods (American white and English), irrespective of ABO group, contain the Rh agglutinin, and these bloods are called Rh-positive. The remaining 15% of persons (Rh-negative), whose red cells lack the Rh agglutinin, are liable to form anti-Rh agglutinins if the Rh agglutinin is introduced into their circulation. This may occur in persons of either sex when Rh-positive blood is transfused, or in a woman who becomes pregnant with a foetus whose blood cells are Rh-positive, the foetus having inherited the Rh agglutinin from the father. When the father is Rh-positive the foetus is not necessarily Rh-positive, however. The Rh agglutinin is inherited by a pair of genes Rh and rh, Rh being dominant. When the mother is Rh-negative (genotype rhrh) and the father Rh-positive (genotype RhRh or Rhrh), all the children will be Rh-positive if the father has the genotype RhRh, but when the father has the genotype Rhrh, each child will have an equal chance of being positive or negative, and there will probably be positive and negative children, although all may be positive or all negative.

A very important aspect of the formation of anti-Rh agglutinins by an Rh-negative person, whether this occurs as a result of pregnancy or of transfusion, lies in the fact that a subsequent transfusion of Rh-positive blood may lead to a severe haemolytic reaction, which may be fatal. Since 85% of bloods are Rh-positive, blood which is selected only on the basis of ABO group compatibility is very likely to prove incompatible in these cases. The only compatible donors are Rh-negative persons of suitable ABO group.

It is of considerable clinical importance to be familiar with the types of case in which the formation of anti-Rh agglutinins should be suspected.

Relation between Iso-immunization of the Mother to the Rh Factor and Erythroblastosis in the Infant

In erythroblastosis foetalis or, to use the more accurate name for the condition, haemolytic disease of the newborn, there is activity of the extramedullary haemopoietic centres (i.e. erythroblastosis) and of the bone marrow, while the peripheral blood shows many nucleated red cells (erythroblastæmia). The use of the term haemolytic disease of the newborn may lead to the confusion of this condition with haemorrhagic disease of the newborn. In the latter condition the common manifestations of melaena and haematemesis are due simply to a deficiency of prothrombin. In haemolytic disease of the newborn, on the other hand, the infant's red cells are broken down by immune agglutinins formed in the mother's circulation during pregnancy. In over 90% of cases the mother is found to be Rh-negative, whereas the father and infant are Rh-positive. During pregnancy the mother produces anti-Rh agglutinins, which pass from the maternal circulation into the foetal circulation and cause the foetal erythrocytes.

The presence at or shortly after birth of either (a) jaundice which rapidly deepens to an intense degree, or (b) marked oedema, or (c) severe anaemia, has led to the identification of three clinical types of erythroblastosis—icterus gravis, hydrops foetalis, and congenital haemolytic anaemia. While clear-cut examples of these types are easy to recognize, the symptoms of haemolytic disease of the newborn are so variable that diagnosis is sometimes difficult. For instance, at birth the infant may appear to be normal and not develop jaundice or anaemia until later; moreover, the jaundice may ever be severe. Again, although a marked degree of erythroblastæmia is frequently present, the number of nucleated red cells varies from time to time and from patient to patient; indeed, at birth there may not be any nucleated red cells in the blood stream, and sometimes erythroblastæmia may not occur in congenital haemolytic anaemia until after recovery has begun. On the other hand, the blood of the healthy newborn full-term child may sometimes contain many erythroblasts as to appear pathological.

Many infants with haemolytic disease are stillborn, often prematurely, and may be oedematous; nevertheless, as is the case with the full-term child, the stillborn infant may be outwardly normal. When there is no other obvious cause of foetal morbidity, it is probably wise to suspect the existence of erythroblastosis foetalis and assume, for purposes of treatment at least, that the mother has

become immunized to the Rh antigen, and therefore to avoid transfusion of blood, unless known Rh-negative blood of suitable ABO group is available.

There is at present no known method of preventing the occurrence of erythroblastosis, and when a woman has given birth to an affected child, subsequent children are also likely to be affected. The mode of inheritance of the Rh factor should always be borne in mind, however, when giving a prognosis with regard to future children in the families in which Rh is involved, because if a subsequent child is Rh-negative it will be unaffected; for reasons, at present understood, occasionally even subsequent Rh+ child may be unaffected.

Iso-immunization to the Rh Factor following Transfusion

The transfusion, and particularly the repeated transfusion, of Rh-positive blood to Rh-negative recipients of either sex may cause development of anti-Rh agglutinins in the recipient's circulation and thus lead to the premature destruction of the donor blood cells. At first this process may be entirely silent; alternatively the onset of evidence of the increased rate of elimination of the transfused blood may be a failure of the recipient's haemoglobin concentration to increase following transfusion. If further transfusions of Rh-positive blood are given, however, the reactions become increasingly severe, the destruction of the donor blood cells is more rapid, and the recipient may become jaundiced or even develop haemoglobinuria. Sometimes no immediate reaction to the transfusion is observed, but the recipient develops oliguria after transfusion and passes into state of uraemia some days after transfusion. The occurrence of any of these signs, and particularly the increasingly unfavourable response to transfusion, should always suggest the possibility that the recipient has become immunized to the Rh factor, provided the course that the possibility of incompatibility due to faulty ABO grouping has been excluded.

In practice, serious haemolytic transfusion reactions due to the Rh factor are considerably more common in the group of women who become immunized as a result of pregnancy than in the group of persons of both sexes who become immunized as a result of transfusion.

Recommendations

Ideally, Rh-negative persons should be transfused only with Rh-negative blood. At present, however, this ideal may be regarded as impracticable because of the technical difficulties of making Rh grouping tests on a large scale and because of the greater administrative difficulty of keeping a sufficient number of Rh-negative blood in small blood banks to serve the needs of all Rh-negative recipients.

(1) Mothers of infants which manifest signs of erythroblastosis should not be transfused with blood unless known Rh-negative blood of suitable ABO group is available. In a case of urgency plasma serum should be used for transfusion.

(2) When transfusions are given to infants affected with erythroblastosis foetalis, blood from a group O Rh-negative donor should be used whenever possible. If no such donor is available, the mother's red cells, if of suitable ABO group, may be used, but the cells must first be washed free from plasma and suspended in physiological saline. When this, too, is impracticable and transfusion is urgent owing to the anaemic state of the child, a donor of group O, taken at random, may have to be used, although it should be realized that such blood will usually be Rh-positive, and that it may produce a transient jaundice in the infant. In these circumstances it is better to seek a donor among the mother's relatives than to use the father or his relatives. The blood must be introduced intravenously and not intramuscularly, and the transfusion should be given at the earliest possible moment after the diagnosis of haemolytic disease has been made. If previous infants in a family are known to have been affected, the cord blood should be examined for the degree of erythroblastæmia with a view to establishing the diagnosis as early as possible.

(3) Recipients of either sex who, from their response to previous transfusions, are suspected of having become immunized to the Rh factor should receive no further transfusions (unless Rh-negative blood of suitable ABO group is available) until the cause of the unfavourable response to the previous transfusion has been investigated.

(4) Although, when the patient's serum contains anti-Rh agglutinins, it is often possible to select a compatible donor by testing the patient's serum against a number of different bloods of suitable ABO (but unknown Rh) group, reliable results are very difficult to obtain without considerable experience, and it is strongly recommended that this method should not be attempted by persons who lack experience.

(5) In all these circumstances contact should be made as soon as possible with the nearest blood depot or regional transfusion officer. Even when the person suspected of having become immunized to the Rh factor does not require transfusion, it is hoped that contact will be made so that serological tests can be carried out. It is difficult to secure enough serum for testing persons, for only a small proportion of persons who become immunized to the Rh factor develop anti-Rh agglutinins which are of sufficient potency for this

purpose. It is therefore of great importance that clinicians should co-operate by sending samples of blood from their cases for testing, and by persuading those patients who have strong anti-Rh agglutinins to give some of their blood in order to secure a supply of test sera.

(6) When it is discovered that a person has become sensitized to the Rh agglutinin a statement of this finding should be handed to the person concerned, and she (or he) should be told to carry this statement with her (or his) identity card or blood group card and to show it to her (or his) doctor.

Reports of Societies

FUNCTIONAL DISEASES OF COLON AND RECTUM

A discussion on functional diseases of colon and rectum took place in the Section of Proctology of the Royal Society of Medicine on June 9. Mr. E. T. C. MILLIGAN presided, and he four openers were physicians and psychiatrists.

Sir ARTHUR HURST, after describing the physiology of the colon and rectum, said that the conditioned reflex which led to regular morning defaecation might begin in the education of the infant and develop in such a way that the normal individual as he got older did not think about it at all. The most common cause of what was called constipation, especially in women, was neglect of the normal call to defaecate. If the prompting was not acted upon the muscular wall of the rectum relaxed, and the desire to defaecate disappeared and did not return until the next quantity of faeces passed into the rectum. If there was persistent neglect of the call the rectum became completely relaxed and distended. Well over half the cases of constipation were caused not by any deficiency in the activity of the colon itself but by interference with the reflex. Another large group of people imagined themselves to be constipated when they were not. Many of those who went to the doctor for what they called constipation would say that they had a liquid stool; that for years they had not passed a solid motion. These were the people who had been taking the aperients which figured so largely in the advertisement columns of the newspapers. The symptoms of auto-intoxication were not produced by constipation; they were the result of diarrhoea brought about by aperients. Yet another cause of upset of normal bowel activity was the procedure common some years ago and now revived, known as colon lavage: not the old-fashioned Plombières couche, but successive washings out by one pipe after another, taking perhaps a couple of hours in all, in the vain expectation that eventually clear water would be returned. This procedure ignored the physiological fact that faeces were constantly coming down and mixing with the water. A point to remember was that mucus could only be regarded as significant of a pathological condition if it was present with spontaneous diarrhoea. With a loose stool caused by an aperient it was merely a protective secretion and of no importance. Mucous colitis was an imaginary complaint based on a wrong diagnosis; it was due to the idea that the presence of mucus was itself significant of disease.

The taking of aperients was the commonest cause of the general low abdominal pain associated with spasm. But when such conditions as real ulcerative colitis and diverticulitis were excluded there remained a small number of cases in which colon spasm was the primary thing—a condition corresponding in some respects to asthma, and not easy to diagnose or treat. He warned strongly against x-ray examination as a method of diagnosis. Finally Sir Arthur Hurst mentioned paroxysmal proctalgia, first described as rectal crises of non-tubercular origin. The patient at intervals had severe pain, always perineal, not at the anus but apparently three or four inches up the rectum. Usually it went off spontaneously after ten minutes or a quarter of an hour. It was not associated with any particular condition of the bowel, but often with sexual activity. It was almost certainly due to a muscular contraction, probably at the junction of the pelvic colon and rectum. Doctor-patients had obtained relief by having at their bedside an enema syringe and blowing air up the rectum.

The Psychological Approach

Dr. HENRY WILSON, in discussing the effect of temperament upon the colon, pictured two extremes of temperamental type—the jolly, happy-go-lucky individual with external interests, who never thought of his bowels at all, and the highly self-conscious and introspective person with rigid standards for himself and others. When the former had intestinal symptoms, organic disease might be expected; when the latter, no physical disorder apart from over-activity of the central autonomic system. The patient ought to be asked, "How do you think your condition is caused?" If some time were spent in listening to his story and getting a picture of the ordering of his life, it might be found that his symptoms were escapist, or that his central autonomic system was subjected to some strain owing to the emotional rigidity and stress of his life. It was important to remember how the hypochondriac enjoyed the display of the details of his bowel movements. Often he was leading a self-thwarting existence; the interest which the normal individual derived from his family and his work were blocked. In dealing with such a patient the recommendations about lavatory arrangements should be of the shortest and the ritualistic directions about drugs, their times and seasons, should be as simple as possible. As for drugs, barbiturates in quite small doses were preferable because they lessened the tension in many cases in which the autonomic system was too active on account of the patient's general abnormal outlook on life. The encouragement of centrifugal interests among such people was as necessary a part of social medicine as occupational therapy in cases of mental disorder.

Dr. GEOFFREY EVANS said he had been taught by an eminent surgeon many years ago that it was of no use to try to get normal action of the bowels in a constipated person unless the anal margin and canal were structurally intact, and therefore he first of all considered piles and such conditions. After this he was accustomed to give his patients a leaflet containing the principles of treatment of chronic constipation which he had learned from Sir Arthur Hurst. They must learn self-knowledge, self-reverence, and self-control. As for the role of the proctologist, this should include rehabilitation. He should not let his patient go until normal bowel function had been restored—i.e., evacuation of a solid stool with a sense of completion. In the practice of medicine perfection of function was as important as regularity. Incomplete evacuation was a failure of perfection in function such as, in another field, was found in the case of a bladder obstructed by an enlarged prostate. As for bad habits, the worst of these was the early morning rush, leading to neglect of the call for defaecation. Another cause of constipation, not always appreciated, was fatigue. He believed that a number of cases of constipation were congenital. He had seen the condition inherited through at least three generations. Physiological disorders were inheritable just as much as anatomical peculiarities. Another functional disease of the sigmoid was a neuro-secretory disorder—a dry sigmoid. He believed that that was the true aetiology of a few cases of ulcerative colitis—a catarrhal sigmoiditis due to the dry sigmoid—the neuro-secretory disorder of the sigmoid going on to an ulcerative sigmoiditis and then spreading up the bowel. These were the cases which did well with a wash-out.

The Costive Patient

Dr. E. H. LARKIN said that in cases of persistent pain in the rectum for which no cause could be found psychiatry could often be of assistance. It was necessary for the physician to detach his mind from the local symptoms and to view the patient as a whole. The common characteristic of the chronic costive would be found to be fear. He was always anxious and afraid for himself in general and for his bowels in particular. All chronic costives were neurotics. Psycho-analysis might reveal why the anxiety had become fixed on one sort of symptom in a particular case. An immediate worry might cause pain or disordered function, and a chronic worry chronic pain and dysfunction. One trouble was that while "a lot of people's emotions flowed to their bowels," when they went to a proctologist they had no ready-made language nor any facts of common experience upon which to rely, unlike patients who suffered from, say, some chest complaint. Their minds were

concentrated upon their trouble, but their tongues could not be glib about it. Sometimes the obsession was removed by a quite different adjustment. He cured one case of obstinate constipation by insisting that the patient should get an accountant to straighten out certain difficulties into which he had fallen with the tax authorities. There was no mistaking these afflicted patients—the wrinkling of the forehead, the lustreless eyes, the drooping corners of the mouth, the hunched shoulders, the cold and lifeless hands, the easy loss of temper, the lack of appetite. True depression could be diagnosed in nearly every one of these cases. It was the depression that needed treating, and the treatment was rest, secured by sedatives and reassurance.

The remainder of the discussion resolved itself largely into a recital of personal experiences with particular patients. Mr. LAWRENCE ABEL said that the proctologists who stayed in London during the air bombardment of 1940-1 would have gone out of practice had it not been for "siren diarrhoea." Dr. WESTMANN said that functional diseases of the rectum could be brought into parallel with functional disorders of other organs, especially in the female. Research work in endocrinology should be watched and encouraged. Dr. PARKES WEBER agreed that some printed instructions such as Dr. Geoffrey Evans gave to his patients were likely to be extremely useful, but he would go further and say that it was young, healthy, non-neurotic people who should have the benefit of such instructions. It was such people who were most tempted to neglect the calls of Nature and to draw upon their reserves of mental and bodily health. He believed that paroxysmal proctalgia was merely one form of unstripped muscular spasm in the abdomen. One ought to try to get at its starting-point, which might possibly be an enlarged prostate or some abnormality of the prostate before actual enlargement was reached. Some people were so constituted as to have the potentiality of painful spasm in the abdomen. They were born with it, and it was necessary in each of these cases to try to learn everything possible about it and so to take measures for its prevention or relief.

SCOTTISH DIPHTHERIA IMMUNIZATION CAMPAIGN

At a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on May 28, with Dr. E. H. R. HARRIES in the chair, Sir ALEXANDER RUSSELL described the organization and results of the Scottish diphtheria immunization campaign, 1941-2. He began by exhibiting a graph showing the diphtheria death rate for Scotland from 1855 to the present year. The enormous death rates of 1862-5 dwarfed all later figures. From 1873 to 1933 the rate had continuously gone down, and since 1933 it had been stationary, except for the epidemic wave of 1940. A large fall in the rate occurred in 1894-7, immediately following the passing of the Notification of Infectious Diseases Act, which made diphtheria and membranous croup optionally notifiable. The notifications of diphtheria in Scotland, which in 1935 were 11,065, rose to 15,711 in 1940, and fell to 13,586 in 1941, 10,614 in 1942, and to 2,787 in the first quarter of 1943. The immunization campaign opened at the end of November, 1940 (it should, of course, have opened much earlier in the year). All local authorities were supplied with free issues of toxoids A.P.T. and T.A.F. It is said that with the former toxoid, reactions in the older age groups were more likely to occur, but this form had been used for all age groups, and even in older children had caused few untoward reactions. Only in one instance was the reaction such that the family doctor—who had not given the inoculation—felt impelled to notify the case, quite incorrectly, as acute erysipelas. Among the 745,928 children inoculated in 1941-2 (211,335 pre-school and 534,593 school) there was hardly a case of reaction which gave anxiety to parents or doctors. Eight children in three different areas developed somewhat similar symptoms some time after inoculation with A.P.T. The symptoms consisted of paralysis of certain arm and shoulder muscles and appeared from 14 to 25 days after the second injection of toxoid. Six of the eight children had made a complete or almost complete recovery; the other two were still under treatment.

Effectiveness of Immunization

There had been neither time nor opportunity for carrying out post-Schick tests except locally. In one series of tests at Kilmarnock in over 4,000 children 97.2% of the children under 5 to 10 years and 96.9% of those of 10 and over gave negative reaction. In Dundee, where the tests were made only two months after the last injection, the percentages of negative responses for the two age groups were respectively 90.4 and 93, while for the children under 5 the percentage was 94. From examination of swabs in the case of 796 children in Dundee there was no evidence that an abnormal carrier rate existed among the immunized.

A striking variation had taken place since 1939 in the strain of the organism. Figures for Edinburgh showed that while in 1936 *gravis* infections amounted to less than 10% of the total, in 1939 these accounted for 60 to 70%, and in his 1940 report Sir Alexander Macgregor, M.O.H. for Glasgow, also mentioned the rise in frequency of *gravis* infections. In Dundee the *gravis* type became much more prevalent during the autumn of 1940, and the new type had remained strikingly predominant. It could be said that to-day, over a large part of Scotland diphtheria was a different malady from that which had prevailed in the past. Another change had been in age incidence with a marked decrease in the percentage of cases among those aged from 5 to 15, and an equally marked increase among those over 15. It was tempting to suggest that this change of age incidence was associated with mass immunization of the school population, but a somewhat similar change was recorded thirty years ago by Dr. A. K. Chalmers, then M.O.H. for Glasgow.

Mortality Statistics

Turning to mortality statistics, Sir Alexander Russell said that up to the end of March, 1942, it could not be claimed that there had been any remarkable decrease in diphtheria mortality, but a comparison of the figures for succeeding quarters with those for the previous year was instructive:

		Deaths			Deaths
1941	Second quarter	117	1942	Second quarter	57
	Third quarter	88		Third quarter	49
	Fourth quarter	125		Fourth quarter	69
1942	First quarter	115	1943	First quarter	75

The figures for April and May, 1943, suggested that the total for the second quarter would be even lower than for the second quarter of 1942. The case mortality rates for diphtheria in Scotland, which were 19.9% in 1900, had gradually fallen to 4% in 1931, and had remained at that figure for the following ten years, but in 1942 they had dropped suddenly to 2.75%.

In estimating the results of the immunization campaign it could be said that diphtheria had ceased to be a large public health problem in nearly the whole of Scotland. The problem was now confined to the four large cities and to parts of counties lying in the industrial belt. The immunized school child was eight times and the immunized pre-school child about twenty times less prone to attack than the non-immunized. Among immunized children who did contract diphtheria the infection was almost invariably mild, and the complications infrequent. An immunized child was more than one hundred times less likely to die from diphtheria than the non-immunized.

The Situation in England

Dr. J. A. H. BRINCKER added a few remarks on the situation in England. Up to the end of 1942 the number of immunized children according to returns by the local authorities in England and Wales was 3,748,000, which, taking the child population under 15 to be 8,250,000, excluding children under 1 year old, was 45%. He gave reasons for supposing, however, that the real figure was much more like 5,000,000. Certain figures for England and Wales in 1942 suggested that, for every one immunized child who contracted the disease, 5.6 non-immunized children contracted it, and that so far as mortality was concerned the proportion was 1:11. But these figures were far from satisfactory, and the story was very different in particular localities where the medical officer of health had been careful in collecting the facts. In Northamptonshire, for example, for every one immunized child who was notified there were 194 non-immunized children who contracted the disease, and there were no deaths at all among the immunized children.

Correspondence

Conditions for Good Work

SIR,—For the majority of our profession engaged in medical practice our patients leave us little time to think of future standards of remuneration, of pensions, or whether it would be advantageous to crowd the random night calls of a month to one whole night on duty per month. Such reforms don't owe the average "medical" much, although they always figure prominently in official publications, and for obvious reasons. There is, however, one constant refrain on the lips of men I meet in practice: "What we want is conditions that make good work possible." It was the one longing in peace, and the war has intensified it. Although, of course, it may not always be expressed in those precise words, few will deny that it is the dominant dissatisfaction. This letter stresses the chief barriers to progress.

"Numbers" are the chief obstacle. The panel legislates for a maximum of patients, which, coupled with the relatives of the insured and those of better means, is about twice the number the doctor can treat efficiently. Though incessantly taught during training that "successful treatment consists in diagnosis, diagnosis, and diagnosis," a young doctor finds that practice makes a mockery of the aphorism. At his "surgery" the doctor's one idea is how to dispatch the patient quickly and so get in the other forty or fifty thronging the waiting-room. With such interviews even the shrewdest doctor is bound to err sometimes, for "more things are missed by not looking than by not knowing." This scandal will remain whatever the doctor is paid. The remedy lies not with the Mint but with the medical schools, and it will take many years for them to double the number in our profession and so furnish a decent proportion between doctor and patients. Aggravating the foregoing is the unduly high proportion of trivial complaints, however insignificant, each must be "seen," for a serious malady may lurk among them. The minutes so occupied soon mount up to an hour, and those for whom succour is vital are kept waiting and will miss the deliberation and care they merit. The greatly increased demand for certificates is an even worse abuse of medical talent.

This brings us to the second major grouse. "When the interesting case does arise there is no time to go into it properly." Instead of studying it in detail the doctor temporizes by a bottle of medicine or has to send the patient into hospital and so loses sight of him. The obvious remedy is to copy in the panel sphere the satisfying procedure of private practice. Then the doctor would have plenty of time for full consideration of cases, and would automatically attend special consultations, and be expected to share in treatment if the patient entered hospital. This ensures the continuity of care and interest by the family doctor.

Thirdly, the doctor is thwarted by lack of adequate home help for invalids. This causes vexation and disappointment when the illness is one which is well within his competence to treat. We need a "general practice annexe" to major hospitals for such patients. The general practitioner would continue to be in sole charge; the nursing costs would be shared with the hospital—a mutually economical arrangement; specialist services, should need arise, would be close at hand.

Fourthly, "divided responsibility" breeds discontent. Advice by one doctor at the welfare clinic or in school during the day is apt to conflict with that of the family doctor to whom the parents may resort during that evening. One captain should guide the ship of health. Having sole responsibility and the patient's welfare entirely dependent on him put the doctor on his mettle.

The Government that removes these bad conditions will confer a genuine boon on our profession and an infinite blessing on the sick. Left, they induce a sense of frustration disheartening to those ardently seeking efficiency in a vital national service.—I am, etc.,

A. WILFRID ADAMS.

The Government's Proposals

SIR,—The publication of Dr. Grasse's letter (May 29, p. 679) was most opportune. After a careful reading of Dr. Hill's statement of May 16 one is forced to the conclusion that our representatives are not prepared to see the benefits which the Government's proposals offer to both the public and the profession. There is no reason why patients attending a health centre should not see the doctor of their choice provided they attend during his consulting hours, just as it is now possible for a patient to see a particular consultant at a hospital out-patient department. Should treatment be required outside the usual consulting hours it is probable that it would be for an accident or some emergency, in which case prompt attention would be the patient's chief concern. The patient would also have the satisfaction of knowing that there was a doctor readily available at all times. Under the existing system there are partnerships where "free choice of doctor" is present only to a limited extent.

As salaried public servants the profession would probably be more respected. Healthy competition may be a good thing, but there is no sharp dividing line between this and other less ethical methods of maintaining or increasing the income from a practice. The suggested remuneration would appear to be adequate when it is considered that it would be net income and that we should be free from practice expenses, mortgage interest, and capital repayments. Although the salary would mean a reduction of income, it is possible that many practitioners might consider this a reasonable price to pay for freedom from worry. On the other hand, any compromise such as a further extension of N.H.I. would only give us the worst of both worlds. The proposed arrangements should help doctors' wives, two of whom have written to the *Supplement*, as even in peacetime they will, under the present system, continue to live "over the shop"; also to obtain domestic staff will still be a problem. At health centres it would be possible to employ a regular and trained staff for clerical and domestic duties, and a system of shift work could be adopted.

It has been stated that there is some ill-founded optimism regarding the possibility of improving working conditions as there will be no great accession to the ranks of doctors. Surely it would be better to have a definite rota of duties involving more work if it gave us the satisfaction of knowing that there would be some time which we could call our own. As there are men from "single-handed" practices in the Forces who consider that the Government's proposals are being opposed by some older men who are at home in well-established practices, it is to be hoped that all will be given an opportunity to record their wishes before this promising scheme is finally rejected.—I am, etc.,

JOHN V. LAVERICK.
Surgeon Lieutenant, R.N.V.R.

Labour and State Medicine

SIR,—There must somewhere be a fable about a gathering of the animals for the purpose of setting up a community in which it is recognized that each member will have to give up some of his ways in return for the others doing likewise; but all in vain, for none of the delegates would pledge its kind to surrender its predatory habits until all the other animals had done so first.

It is this sort of progress that is contemplated by the writer of the article under the above title (June 19, p. 761) when he suggests to "our would-be political masters" (perhaps forgetting for the moment the strictly non-political attitude of the *Journal*) that "the house should be set in order first, and the people in it fed and clothed properly, before calling in the doctor." If the patient can get well before calling in the doctor, so much the better for the patient, if not for the doctor. But what if he cannot? A state of society which can be set in order before calling in the doctor is one which, *ex hypothesi*, does not need the doctor at all; and, conversely, a state of society in which the doctor plays a necessary part—that is to say, every state of society hitherto known—cannot be set in order without calling in the doctor.

Thus the writer of the article scores what would seem to be a bad point by attributing to the policy of "our would-be

political masters" the very error into which he has fallen himself—that of isolating a single aspect of the programme of reconstruction and treating it as though it were the entire programme itself. In a society in which the relationship of the doctor to his patient changes simultaneously with the relationship of every man's benefits (the doctor's included) to his needs, it will not be true to say that "the doctors will remain the same men" or that "their patients will (in some respects of health and sickness) remain the same men, women, and children."

As to the incentive to work, those many doctors whose impulse to work comes from their enthusiasm for their vocation will not work with the less encouragement because at the health centre they will be provided with the best and most modern equipment and adequate and efficient assistance, an absence of over-strain, and no temptation to waste their time on wealthy imaginary invalids at the expense of the panel queue. Those few who depend for their incentive on financial reward will find their drive in other directions in a world in which what change is left out of the taxes will only buy a very limited amount of comfort and prestige.—I am, etc.,

Great Bookham.

RICHARD A. MANCLARK.

Service under a Lay Council

SIR.—Your leading article on June 19 (p. 761) prompts me to put on record one little incident which occurred while I was a member (Independent) of a town council in Scotland (I have been a member of two town councils and two county councils) where there was a large Labour majority. There was a vacancy for a medical officer of health, and I was a member of the selection committee. We met, and, from the 12 to 14 applications received, formed a "short list" of 5 for interview. The first doctor interviewed was the youngest applicant, and he expatiated greatly on his wide experience in the serum treatment of scarlet fever. I may mention here that I maintained strict silence throughout all the interviews. A later candidate was somewhat taken aback when a member of the committee suddenly asked: "Now, doctor, how do you treat your scarlet fevers?" I must confess that at this juncture I gave the doctor a wink, and here I might mention that I knew none of the applicants nor had I ever seen any of them before, although they were aware of the fact that there was a doctor on the selection committee. The wink doubtless disclosed my identity. The question was asked by a man who once upon a time went round the town with a fruit cart and then later became an agent for the Co-operative Insurance Society.

I would not like to have been in the shoes of any of those medical men who, under the present ridiculous system, were forced to answer the questions (many medical) from the lips of this semi-ignorant and semi-illiterate body of councillors. It is evident that the Labour Party desires not only to perpetuate but to extend farcical local government. I suggest a qualifying examination for prospective town and county councillors as a pre-requisite to good local government.

For myself I am prepared to play my part in any State Medical Service enacted by and under the control of the session, but with the memory of my experience of present local government I will oppose to the bitter end any attempt to force me to serve under a town or county council. I authorize you, Sir, to give my name and address to any medical man who desires further information relative to my own experience with lay committees; but at present I hope I may, for obvious reasons, be allowed to sign as—

FORMER COUNCILLOR.

Medicine and Politics

SIR.—Your correspondents who criticize my two articles appear not to realize that science and knowledge are far more important than any political consideration. When German scientists state that psychoneurosis is unknown in the German Army they indicate the subservience of German science to German politics, and are rightly regarded with contempt. Religions and political creeds have often in this way attempted to pervert and to bend scientific truth. To-day's political creeds, of whatever colour, have not suddenly achieved omniscience and intellectual fairness. Knowledge, or science, is

greater than nationalism or patriotism, and *a fortiori* is greater than any Government of the day. Still greater is it than capitalism, socialism, Marxism, or any other party belief.

I suspect that my critics are tied to political placenta by party umbilical cords, and they fear any threat to the channels of intellectual nutrition. They are attempting to serve two masters—science and politics—or, by rationalization, have persuaded themselves that politics and science are one and the same thing. I believe that doctors, in order to serve the public adequately, must follow science alone, and must retain the right of independent criticism of all political parties or dogms. They must serve the public to the best of their ability, but this duty to the politically expressed wishes of the country applies only so long as these wishes do not run counter to accepted scientific principles. The examples of Galileo, Freud and Einstein illustrate this point.

When Mr. Somerville Hastings (June 19, p. 766) attempts to defend politicians I do not quite know where to take him for he previously attempted to deny that municipal medical superintendents had power to interfere with the practice of their medical staffs by quoting the L.C.C. rule that the medical superintendent shall "organize and supervise the work of the medical staff of the hospital and be responsible for the day and punctual attendance upon the patients and for the giving of the requisite directions as to their treatment, nursing, and diet by the medical officers, and for the condition of the wards." All my statements regarding the political control of medical officers in the L.C.C. and other municipal hospitals could have equally been confirmed. He says that politicians are as mistrustful of doctors as the latter are of politicians. The mistrust felt by politicians is the fear that ignorance is of knowledge. The mistrust that the medical profession has of politicians is founded upon bitter experience of political theory and practice.

Mr. Hastings regards as "arrant nonsense" my statement that intellectual activities are not encouraged by politicians. I would ask him to look into the question of the municipal achievements in that most important of intellectual activities—education. The classes are universally too big, the teachers are scandalously underpaid, and the percentage of subsequent illiteracy is not negligible. Either the politicians concerned are ignorant, or they are incompetent, or they are dishonest. In any case they can hardly be said to encourage intellectual activity, which is exactly what I affirmed. The same educational conditions exist under Tory or under Socialist control. Therefore, it is not without reason that doctors who desire the best treatment for the greatest number look with some degree of mistrust at the possibility of political control of medical practice.

It is the plain duty of those who disagree with my affirmation that medical science must not be politically controlled either to state frankly that they disagree and that they wish the politicians to run medical affairs or to prove that a State service can be devised in which complete professional freedom may continue to exist.

Dr. Gainsborough's letter (June 12, p. 738) is so full of the "skittle technique"—ascribing to me supposititious statements or opinions, and then bowling them triumphantly down—that I suspect his political feelings have coloured his scientific judgment. I do not understand his oratorical flights or his pharmacological parentheses.—I am, etc.,

London, W.1.

GROTFREY BOURNE.

Psychiatry in General Hospitals

SIR.—The solution of the problem of mental hospital and neuropsychiatric wards in general hospitals raised by Dr. Dalton Sands (May 22, p. 628) surely lies in the hands of the mental hospitals themselves. It is because, in general, mental hospitals are so deplorably behind the times, housed usually in overcrowded barrack-like buildings which petrify the ideas of the middle of last century, terribly under-staffed in doctors and nurses, that the growth of hospitals like the Sutton Emergency Hospital is at all possible or necessary. The measure of success attained by Dr. Sands is also the measure of the failure of the L.C.C. to adapt its mental hospitals to present-day needs. It is most urgently desirable that mental hospitals throughout the country should wake up in time and make themselves into

pleasant places, utilizing every available method of treatment to a far greater degree than is customary to-day. To achieve his end a number of reforms are necessary:

1. The repeal of the Lunacy Act, 1890, including abolition of the Board of Control.

2. Certification to be entirely medical in character, along the lines of the present temporary certification, with the Courts of Justice exercising oversight to prevent wrong certification.

3. As an early post-war measure the pulling down of all present mental hospitals and their substitution by temporary hospitals consisting of isolated single-story wards, each holding 25 patients at the most. This will be the solution to Dr. Crichton Miller's (?) fundamental issue of the locked gate (June 26, p. 800). Not more than 5% of the patients in any mental hospital to-day need be in locked wards, but because we are condemned to work in out-moded buildings built by our great-grandfathers we still have to keep the majority locked up. Like the stopped window the locked door is, in general, as out of date as the padded room. These temporary hospitals should be built on the edges of the towns they serve and not isolated in the depths of the countryside. They should have a life of about thirty years and should then be pulled down and rebuilt in accordance with the current ideas of the day.

4. All mental defectives should be removed from mental hospitals to suitable institutions. At present far too many of our beds are filled by defectives who seem to have given a little trouble at a colony for mental defectives and consequently promptly certified and sent to a mental hospital for the rest of their days. Institutions for defectives should be "up-graded" and compelled to take all types of defectives, including psychotic ones for whom adequate psychiatric treatment in the institution should be available.

The adoption of these reforms would constitute a far more radical solution than would the setting up of neuropsychiatric wards in general hospitals. Dr. Minski (p. 800) cannot have it both ways, and despite his desire not to see mental hospitals used "solely as dumping grounds for the chronic, incurable patient," the widespread adoption of neuropsychiatric wards must inevitably lead to this. What sort of patients would Dr. Minski send to the mental hospitals?

A few other matters raised in the correspondence following Dr. Sands's article call for comment. The question of stigma is not peculiar to mental disease. It is attached to any disease of poor prognosis. Malignant disease, tuberculosis, syphilis, the typhoid carrier state, are all subject to it. Make our mental hospitals the curative places they can become and the stigma attached to them will largely disappear.

Dr. Minski's critical letter is itself open to criticism, especially his reference to the unfortunate use of the word "proved" by Drs. Rees and Shepley. In neither letter is it stated what these modern methods of treatment are supposed to have "proved." Surely "to prove" is a transitive verb. Presumably Drs. Rees and Shepley mean that these methods have proved of value in the treatment of patients in certain mental hospitals. Few people would agree with Dr. Minski that this is a "rather sweeping statement." Obviously the methods are still in the experimental stage and will, we hope, soon be replaced by more kindly ones, but the antithesis made by Dr. Minski is a false one. If Dr. Minski wishes to know why the number of voluntary patients at Warrington Park is increasing so rapidly I would advise him to visit the hospital. The visit will provide an adequate answer to his question.

Incidentally, the attitude of what one might term the "Maudsley-Tavistock" group towards the orthodox mental hospitals is in itself an interesting psychological, if not a psychiatric, problem. Adler has a word for it, I believe.—I am, etc.,

Joint Counties Mental Hospital, Carmarthen.

A. M. SPENCER.

Special Clinics

SIR,—I agree heartily with Dr. R. H. P. Hick's annoyance (June 5, p. 707) with the Family Planning Association for starting yet another kind of special clinic for work which G.P.s ought to do. But it must be admitted that Dr. Joan Malleson (June 19, p. 769) has dealt him a heavy blow in reply. We family doctors, if we are honest, must admit that one factor in the growth of the special clinics has been the disinclination and incompetence of many of us for the kinds of work they do. Let any G.P. who doubts this put it to the test as follows: Revise, if necessary, his knowledge of infant feeding and mothercraft by careful study of one modern textbook, buy some

scales, and then start a weekly baby clinic at his own surgery. Within a year not one of the mothers in his practice, whatever her income, will use the infant welfare centre, and—dare I say it?—they will all have finer babies than those who do.—I am, etc.,

Cambridge.

H. R. YOUNGMAN.

The Cult of Negative Health

SIR,—The letter of Dr. R. E. Lucas (June 19, p. 766) is opportune. We cannot be reminded too often that the living organism requires, if it is to thrive, an environment sufficiently unfavourable to provide a constant stimulus and challenge. Without this it becomes fat and soft and a prey to disease and decay. In the human being added symptoms are a restless discontent and a seeking after artificial pleasures. The principle applies in all spheres of life, and while it is right to recognize this inner paradox, it would be a pity to ignore the more remote but not less important effects in social organization. Not only has a greatly improved standard of health been accompanied by an increasing tendency to hypochondria, but an equally great improvement in social services and economic security has run parallel with an increased anxiety about the future, with lessened individual self-confidence and self-reliance. This apparent paradox of increased security giving rise to increased anxiety is only comprehensible in the light of the principles on which Dr. Lucas lays stress.

Apart from these general principles we are faced in the years immediately ahead with special problems arising in a generation that has spent its childhood years in the insecurity accompanying evacuation, parental separation, and war conditions generally. It may be confidently anticipated that the childhood insecurity will give rise to consequences demanding exceptional elasticity and adaptability in the social system. Two of such consequences will be a tendency to postulate on the one hand the conditions supposedly causing the sense of inner disquiet, and to demand on the other hand changes in such conditions. Anxiety over ill-health may well be a prominent feature in the picture.

It has been stated that the general practitioner has a vested interest in disease, and that the development of a State Medical Service would solve all our difficulties. But the public health services have thought as much or more in terms of prevention of disease instead of creation of positive health, and have based their appeal, along with the advertisers of potent medicines, upon the people's fear of sickness. The objectives may be beyond criticism; the methods leave much to be desired.

Why is it that "health centre" is already being widely used in connexion with what is little more than an exceptionally well-equipped general practitioner's surgery, more appropriately termed a "sickness clinic"? The healthy have an instinctive and natural antipathy to sickness and the sick, and there is little hope of attracting the fit to a health centre unless health is presented as worth seeking for the joy of living instead of for the avoidance of pain and incapacity. The valuable field work done by the Peckham Pioneer Health Centre seems to be ignored. The evidence presented in the interim report of that centre is invaluable. They noted the danger of persuasion and even of advice. "Individuals, from infants to old people, resent of fail to show any interest in anything initially presented to them through discipline, regulation, or instruction, which is another aspect of authority." And again, in speaking of the "sick," "they can and do, however, their health doctor—he is different. We can't stress this psychological fact too much. The fact that the health doctor has no interest in sickness or its treatment is apparently a major contribution to the attitude of the sufferer. The health doctor is in the position of the solicitor, not the barrister. . . . The one will be approached in faith, the other in fear." Here surely is the crux of the matter, and one not easy for doctors, who have presumably overcome their instinctive aversion to disease, to understand or assess adequately. A real health centre for positive health will become a practical reality as part of a civic cultural and recreational centre only where the health doctor is one of a team, assisting in the development and maintenance of body and mind at the greatest potential

activity. It must, however, be open to doubt whether the existing training of the medical student equips a doctor to play such a part efficiently.—I am, etc.,

London, W.1.

ALAN MABERLY.

SIR,—I hoped and expected that Dr. R. E. Lucas's letter (June 19, p. 766) would have been followed up by others on the same theme by more competent people than myself. May I beg space to put down some of the thoughts that her letter awakes in me?

A little attention will show how many of our daily experiences bear out the thesis put forward by Dr. Lucas. Take the baneful effects of the N.H.I. Acts on doctors and patients alike, both sets of victims witnessing to the degrading effect of the spoon-feeding of the one and the enslavement of the other. All medical men and women who have anything to do with the insured person can testify to the apathy and helplessness of the average specimen, who expects everything to be done for him or her. Consider next the disastrous effects upon the health of both body and mind of women who have practised contraception and the severe limitation of the family. As one who has spent over fifty years in the profession of medicine I say advisedly that the most healthful women in my experience have been those with large families—i.e., those whose path in life was not of the rosiest; they had to "make do," as Dr. Lucas says of the healthy, capable, resourceful, and ingenious countrywoman.

As but a thin partition divides the conscious from the sub-conscious processes of the organism (for surely all reflex acts must at some time in the evolutionary march have been conscious acts) all those capacities for adjustments of the organism by which it has succeeded in the struggle for survival will surely suffer through lack of use, owing to man's over-zealous scientific interference with the interplay of the forces within the organism and those in its environment. A more "jittery" set of psychoneurasthenics than the subjects of six-monthly or yearly anticoryza, or anti-influenza, or anti-pneumonia injections it would be hard to imagine. If Dr. Lucas means something other than this in her fifth paragraph I have misunderstood her, and I would boldly say she ought to mean what I think she does!

The world is filled with the unfit—unfit physically, mentally, and morally—and it would appear to be the aim (and it certainly will be the end) of the planners, Beveridge or other, to add to their numbers. In conclusion I would say that Dr. Lucas's thesis, stated in her second paragraph, deserves the closest attention. What the world needs is a population of educated individuals—not specialists—all of whose "interests, abilities, and energies" are called into play in the process of living.—I am, etc.,

Acton, W.3.

A. R. EATES.

Vesalius and Gray on Anatomy

SIR,—There were two related subjects dealt with in recent numbers of the *Journal* which you failed to connect in your interesting leading article. They were the account of Vesalius's *Fabrica* (June 26, p. 795) and the article on the principles of exercise therapy (June 19, p. 747).

Vesalius, you comment, had the conception of the human "machine" as something at work; it was always living anatomy as he was trying to describe, and the arresting picture of the man walking so gracefully without his skin illustrates it. One can only look at the picture to see the working of the muscles. The rectus femoris brings the leg forward, the gluteus maximus drags, and then both muscles push the body on in our most frequent movement—walking. Yet in the description of the action of these muscles in my copy of Gray's *Anatomy*, 15th edition, the fact that they are used in walking is not mentioned, and there is certainly no mention of the action of the vastus internus which Mr. Nicoll describes and the recognition of which is of such practical importance.

There has been discussion lately on the teaching of anatomy, and here surely is one of the reforms needed—to return to the conception of Vesalius and teach the anatomy of the skeletal system as living anatomy. Perhaps collaboration of an anatomist and an artist might again be fruitful, and the artist should certainly be Walt Disney.—I am, etc.,

Bury St. Edmunds.

S. D. KILNER.

Subcutaneous Emphysema in Small-pox

SIR,—In view of the recent correspondence in your column on the very rare condition non-surgical subcutaneous emphysema in laryngeal diphtheria, it is worth recording that the complication may also occur in small-pox, a disease not mentioned by Dr. J. D. Rolleston in his letter on the subject (Jan. p. 120).

I noted the complication in 1939 in a Chinese male aged 20 was suffering from severe confluent small-pox. He was admitted to hospital desperately ill on the 10th day of the disease, with muffled breath sounds and signs at both lung bases suggestive of bilateral consolidation. Within 48 hours of admission he had developed marked non-surgical subcutaneous emphysema which extended from the roof of the neck to the intercostal space on both sides. As his illness had only lasted a few days it was improbable that necrosis of laryngeal cartilage had caused the condition, though that diagnosis was tentatively made. He died on the 14th day of his illness, and necropsy showed a marked laryngeal enanthem, oedema of the glottis, disseminated bronchopneumonic foci in both lower lobes, and a ruptured emphysematous bulla on the surface of the upper lobe of the right lung. This explanation clearly held good in this case.

I have found no other record of this complication in small-pox.—I am, etc.,

Famagusta, Cyprus.

PAUL WILKINS

Treatment of Cyclic Vomiting

SIR,—It is probable that the distressing complaint of cyclic vomiting will become more common again among children after the present war as it did after the war of 1914-18. The treatment prescribed in textbooks is not hopeful. For instance, Letheby Tidy in *Synopsis of Medicine* (1939) writes: "Cyclic Vomiting.—Best left alone in dark room. No treatment will attack." (Duration 1 to 5 or 6 days.) "Enema. Fomenta or mustard leaf to the epigastrium. Ice to suck or hot water to drink. Food not to be pushed, but attempt small frequent drinks. Salines per rectum if collapsed." (Italics are mine.) The following treatment is simple and logical, and I have found it highly effective in one well-marked case. Nothing is given by the mouth; the bowels are opened by enemata thereafter normal saline with bicarbonate and glucose is given per rectum every two hours by means of a 4-oz. rubber bulb. Desiccation is thus prevented and the patient recovers in a few hours. Oral feeding can be resumed cautiously with lemon or warm beef-tea. Milk must be avoided. Under these conditions the child does not develop that fear of the complaint which is one of the causes of recurrence.—I am, etc.,

Cambridge.

F. H. STEWART

Adder Bite

SIR,—Flying Officer T. M. Davie's interesting letter on adder bite (June 19, p. 769) is likely to induce others, who are confronted with this condition and unable to obtain antivenom, to follow his example of injecting heparin. I should like to point out, however, that injections of heparin are known to produce a condition of increased liability to haemorrhage. The most striking local effect of adder venom is the production of a "haemorrhagic oedema" due to the escape of lymph and blood from the vessels whose endothelium is damaged. The action of the venom, it is difficult to see how heparin—an anticoagulant—can improve the condition of the bitten limb theoretically, at least, it might rather be expected to make it worse.

Among the remote effects observed in severe cases of adder bite, bleeding from the lips and gums, haematemesis, a uterine haemorrhage (intermenstrual) have been noted. In the only necropsy report which I have seen diffuse haemorrhage on the brain surface, haemorrhagic oedema of the lungs, a congestion of the kidneys were among the findings; and was mentioned as noteworthy that "there was no clotting of the blood." This evidence supports the view that it is the haemorrhagic tissue-destroying fraction of the venom that is of importance, and I know of no clinical evidence in support of the idea that intravascular thrombosis—as by a powerful thrombolytic fraction—is to be reckoned with in human beings bitten by *V. berus*. Venoms of some tropical species—e.g., Russell's viper—are known to contain a powerful thrombolytic but argument from analogy of other species is notably unsound.

the case of snake venoms. In view of the known facts should therefore feel inclined not only to doubt the efficacy of heparin as a treatment for adder bite but to regard its use definitely contraindicated. May not Flying Officer Davie'scellent result have been due (1) to the mildness of the case, (2) to his use of hot-kaolin poultices?—I am, etc.,

Terreford.

C. W. WALKER.

Aspirin and Gastric Haemorrhage

SIR.—The question of aspirin and gastric haemorrhage as viewed in Sir Arthur Hurst's letter (June 19, p. 768) raises her relevant aspects of aspirin and its relation to haemorrhage. It would seem possible, in spite of the gastroscopic appearances of the stomach after aspirin ingestion, that the oduction of haemorrhage may be post-absorptive if com-ison and analogy with other aspirin-produced haemorrhages id true. Thus in three cases of epistaxis seen in a short ace of time all were, in my opinion, caused by aspirin, two them being conclusive. In one of these, a child, subsequent periment showed that epistaxis could be produced at will giving aspirin; no evidence of a haemorrhagic tendency ould be discovered otherwise. In the other, an adult with peripiesia, the information was volunteered by the patient that pirin taken for headache always caused epistaxis. In the ird case aspirin had been given liberally.

Aspirin-taking being such a universal habit it is difficult to it a clear idea as to what extent it does produce a haemor-agic tendency, but it would seem necessary in all cases of scure haemorrhage—whether retinal, nasal, gastric, vaginal ncluding menorrhagia), etc.—to inquire if aspirin has been ken. As aspirin can definitely be a cause of extragastric aemorrhage Sir Arthur Hurst's recommendation that it should e taken in powder form to obviate gastric haemorrhage will e of no benefit, especially should the essential lesion prove e a capillary defect due to blood-borne aspirin or its mpounds.—I am, etc.,

Birmingham.

M. HONIGSBERGER, M.R.C.P.

SIR.—In connexion with my letter in your issue of June 19 n aspirin and haematemesis I have been reminded of the astroscopic observations of Douthwaite and Lintott, which emonstrated that calcium acetylsalicylate showed none of the eal irritant action of ordinary aspirin, presumably owing to is ready solubility and consequent rapid dispersion into solu-ion. It can therefore be used without any fear of causing aematemesis.—I am, etc.,

Oxford.

ARTHUR HURST.

Stilboestrol for Breast Tumour

SIR.—Following the annotation on cases of prostatic cancer eated with diethylstilboestrol (Nov. 28, p. 641) I should like o record a case of a tumour of the breast similarly treated.

The patient, a woman of 78 years of age, stated that the lump n her breast had been present for at least ten years. She had con-ealed it and refused all treatment until I saw her at the end of 942. She was emaciated and bed-ridden. In the upper and outer uadrant of the left breast was an offensive fungating tumour the ize of an orange. It bled easily when touched. There were enlarged lands in the axilla. The tumour appeared to be an adenocarcinoma. The patient complained of pain in the region of the left shoulder and p the back of the neck. She also had difficulty in swallowing. She was anaemic: the red corpuscles numbered 3,900,000 per c.mm., he haemoglobin being 53% and poikilocytosis marked.

On Dec. 21 treatment was begun with diethylstilboestrol, 1 mg. hree times daily by the mouth. This caused no nausea, but the ose was not regularly taken. Up to the present 250 mg. have been bsorbed. On Jan. 13 the tumour appeared to be slightly smaller, and the patient improving in health. On March 20 the tumour was finitely smaller, and covered by a thin layer of epithelial cells. o-day, although she is still anaemic and the ankles are swollen, she feels well and has nearly regained her normal weight. She is up and about at her household duties. She has no pain and no difficulty in swallowing. There is a firmly healed non-adherent scar easuring 3 in. by 1½ in. at the site of the tumour. It is surrounded y a ring of dilated blood vessels. There is some thickening behind he anterior axillary fold, due to some lymphatic glands.

The great interest in the case was the clearly visible tumour, which could be seen during its retrogression. It was unfortunate

that microscopical sections could not be obtained, but one felt much indebted to the patient's horror of an operation for an instructive experience.—I am, etc.,

Pittochry.

W. M. BIDEN, M.B.ED.

Economy of Advertising Space

SIR.—Waste of paper and labour results from the repetition of those parts of each advertisement of hospital and public health appointments which could be reduced to a formula. By the co-operation of those advertisers both as regards the date and form of their submissions, a system of classification could be applied, more economical and more immediately intelligible.

Your journal is believed to have such satisfactory relations with other publications as to be able to agree on a matter of this kind, and sufficient strength of character to make it effective in any case in which the need for avoidance of unnecessary waste is not sufficiently appreciated.—I am, etc.,

Chester.

D. STENHOUSE STEWART.

Obituary

R. W. BEESLEY, M.D., M.R.C.P.ED.

Dr. Robert William Beesley, for many years one of the leading practitioners in Bolton, died on June 5 after a short illness at the age of 70. His death removes a distinguished personality from the ranks of the local profession. He was known and esteemed by a very wide circle of friends both in this country and abroad. A native of Preston, he was educated at Preston Grammar School and studied medicine at the University of Edinburgh, winning the Buchanan Scholarship and graduating M.B., C.M. with honours in 1894; he took the M.R.C.P.ED. in 1898, and in the following year won a gold medal for his M.D. thesis. After graduation he served as resident gynaecological physician at the Edinburgh Royal Infirmary and resident physician at the Royal Maternity Hospital. In 1900 he set up in practice at Bolton, and soon afterwards was elected to the honorary staff of the Royal Infirmary, where he had held the post of house-surgeon for some years. When he resigned from the active staff in 1932 on reaching the age limit and was appointed consulting surgeon, the committee recorded its admiration for his great surgical skill and its high appreciation of his splendid work. He was entirely responsible for the first appeal for funds for extension of the hospital in 1919. Dr. Beesley's lucid evidence in Assize and County Courts in connexion with workmen's compensation cases, and also in the coroners' courts, was widely appreciated. He had been a member of the B.M.A. since 1908 and was a Fellow of the Edinburgh Obstetrical Society and the North of England Obstetrical and Gynaecological Society. Outside his professional life he was an enthusiast for the production and use of pure milk, and had three farms where he kept special herds.

Dr. ROBERT REID McLEAN of Harpurhey, Manchester, died on June 3 at the age of 72. He was a native of Belfast and graduated M.B., B.Ch., B.A.O. of the old Royal University of Ireland in 1897 after studying at Queen's College, Belfast. He had practised in the North Manchester district for over 40 years, in the course of which he built up a very large practice. A colleague writes: Dr. McLean's keenness for work and the enthusiasm with which he kept his medical knowledge up to date were a source of inspiration to his partner and many assistants. Latterly he had been a bitter opponent of State Medicine, and the depth of feeling expressed at his death by his very many patients may be an indication of the ties which bind the general practitioner to those he serves.

By the sudden death of Dr. AUGUSTE BOYES, which occurred at her home on June 4 at the age of 67, Dundee loses a well-known personality. She was the daughter of Thomas Gilchrist Boyes, and graduated M.B., Ch.B. at Glasgow in 1899. Her introduction to Dundee was as resident medical officer in the Eastern (now Maryfield) Hospital. Subsequently she held appointments in Shropshire and Surrey, returning to Dundee in 1919 to succeed a prominent medical woman who was retiring from private practice. Dr. Boyes took a keen interest in both the clinical and administrative sides of medicine, and was a

former vice-president of the local branch of the B.M.A. In addition she was an interested member of the Dundee Burgh Insurance Committee, the Panel Committee, and the Mothers' Welfare Advisory Clinic. Not only patients and colleagues but a wide circle of friends will miss Dr. Boyes, as she was the assistant county controller and assistant county director of the Dundee branch of the Red Cross Society and was a member of the Soroptimist Club, the Women Citizens' Association, the Dundee Art Society, the League of Nations Union, and the Orchestral Society, in all of which she took an active part. Dr. Boyes continued her work and interests until the time of her death, which was her wish. Those who knew her well could not visualize her in an enforced inactivity.

The Services

Temp. Surg. Lieut. J. W. Bringan, R.N.V.R., has been mentioned in dispatches for courage, leadership, and skill.

Surg. Lieut.-Cmdr. J. M. Ridyard, R.N.V.R., has been awarded the Norwegian War Medal for good services with the Royal Norwegian Navy.

Major A. C. Crawford, T.D., and Lieut. J. C. B. Whycherley, R.A.M.C., have been mentioned in recognition of gallant and distinguished services in Malta during the period May 1, 1942, to Oct. 22, 1942.

The following have been mentioned in recognition of gallant and distinguished services in the Middle East during the period, May 1, 1942, to Oct. 22, 1942: Brigadiers (temp.) C. Crawford-Jones, C.B.E., and J. Walker, C.B.E., M.C., late R.A.M.C.; Col. E. Scott, D.S.O., T.D., late R.A.M.C.; Brigadier (local) J. A. Sinton, V.C., O.B.E., Col. W. H. Kerr, T.D., Col. (acting) L. M. Rowlette, D.S.O., M.C., and Lieut.-Col. D. Crellin, M.C., R.A.M.C.; Majors (temp. Lieut.-Cols.) A. C. Armstrong, D. L. C. Bingham, J. H. Dunn, J. B. George, H. G. Kirwan-Taylor, R. R. Leaning, O.B.E., J. T. Lewis, C. I. N. Morgan, A. N. B. Odbert, D. U. Owen, T. McK. Robb, W. H. Scriven, A. Simpson-Smith, and V. C. Verbi, R.A.M.C.; Major G. M. Curtois, R.A.M.C.; Capt. (temp. Major) J. Amos, J. B. Bamford, H. B. Craigie, W. S. Gale, R. S. Handley, J. M. Henderson, C. R. Lane, N. A. Lawler, R. B. Martin, J. H. Mayer, J. J. McCarthy, J. W. F. Munden, M. W. C. Oldfield, and G. M. Willoughby, R.A.M.C.; Capt. L. J. Blay, J. Brennan, W. R. S. Doll, A. A. Evangelides, A. P. Grant, H. A. Koretz, D. D. Muir, and H. M. Pickard, R.A.M.C.; Majors (temp. Lieut.-Cols.) H. W. Farrell and G. S. N. Hughes, I.M.S.; Capt. (temp. Major) (acting Lieut.-Col.) L. Morgan, I.M.S.; Capt. (temp. Major) C. H. Bliss and W. J. Young, I.M.S.; Capt. H. Rees and G. R. C. Palmer, I.M.S.; Subadar T. Singh, Jemadur A. F. M. Burhanuddin, and Asst. Surgeon (1st Class) G. T. Wrafter, I.M.D.

CASUALTIES IN THE MEDICAL SERVICES

Wounded.—Capt. J. L. G. Hartley, R.A.M.C., War Subs. Capt. D. F. D. O'Neill, R.A.M.C., Lieut. J. S. Stevenson, R.A.M.C., War Subs. Capt. A. Winder, R.A.M.C.

Prisoner of War.—Capt. A. J. Bailey, R.A.M.C.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The following candidates have been approved at the examination held:

Medicine.—Part II (Principles and Practice of Physic, Pathology, and Surgery): E. L. Arnold, J. Attenborough, E. H. Back, R. A. J. Baily, B. Balme, D. R. Barnes, C. H. Barnett, R. F. Bates, D. L. Bridgewater, Calnan, D. J. Conway, R. P. Cook, J. Davenport, M. B. Devas, D. H. Egan, F. H. Epstein, J. W. Fawcett, R. M. Forrester, H. A. Fraser, M. R. Geake, S. R. S. Godkin, R. N. R. Grant, H. C. Gupta, B. Halah, J. R. Handforth, E. H. Hare, H. Harris, G. Hildick-Smith, J. K. Hinds, P. H. Huggill, E. N. M. Johnston, P. F. Jones, J. O. Laws, J. Lister, J. C. Lloyd, E. Loder, C. S. McKendrick, A. L. McLeod, D. H. Makinson, N. M. Mann, P. G. Mann, A. S. Mason, R. G. May, P. H. Mitchell, P. A. G. Monte, W. J. Naughton, T. Norman, J. E. Oliver, W. J. L. Pain, R. A. Peebles Brown, J. S. Pegum, J. M. Potter, J. R. Robinson, K. C. Robinson, P. H. Rogers, L. A. Roek, P. H. Schurr, O. L. S. Scott, K. H. L. Scragall, E. L. Simons, P. S. Smith, J. S. Staddon, T. R. Steen, R. V. Stone, P. R. Swyer, J. D. Trethowan, L. R. Twentyman, G. S. Uddall, D. Verel, B. J. Webb, D. B. B. Whitehouse, E. H. Williams, P. A. O. Wilson, O. H. Wolff, W. D. Wylie, Wilcoxon, S. M. E. Ambache, J. Hardy, M. Sidgwick, G. C. Thompson, A. B. Willecock, A. S. Willis.

At the Congregation on May 22 the degrees of M.B., B.Chir. (not B.Chir. alone, as printed here on June 12) were conferred upon A. W. Capon, G. F. Pantton, and F. M. P. Eckstein.

UNIVERSITY OF LONDON

At a meeting of the Senate held on June 23 Prof. Frank Horton, Sc.D., F.R.S., was re-elected Vice-Chancellor for the year 1943-4.

The title of Professor Emeritus of the History of Medicine in the University was conferred on Dr. Charles Singer, F.R.C.P., on his

retirement from the Chair of the History of Medicine at University College.

The additional M.B., B.S. Examination to be held in 1943 began on Monday, Jan. 31.

The degree of D.Sc. has been conferred upon Miss Emmy Klieneberger-Lister Institute of Preventive Medicine; Mr. W. T. Russell, a teacher at the London School of Hygiene and Tropical Medicine; and T. E. Wallis, a Reader at the College of the Pharmaceutical Society.

UNIVERSITY OF GLASGOW

At a graduation ceremony on June 25 the following medical degrees were conferred:

M.D.—1 Archibald Dick, Hugh Stewart.

1 With high commendation.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

On July 1 five Fellows were elected into the Council to fill vacancies caused by the retirement in rotation of Sir C. Wallace, Bt., and Prof. Seymour Barling, by the death of Mr. Braithwaite, and by the resignation of Mr. W. Sampson II and Sir Hugh Lett, Bt. The following Fellows were elected:

PHILIP HENRY MITCHNER, C.B.E. (St. Thomas's)
REGINALD WATSON-JONES (Royal Infirmary, Liverpool)
JAMES PATERSON ROSS (St. Bartholomew's)
ARTHUR TUDOR EDWARDS (The London and Brompton Hospitals)
LAMBERT CHARLES ROGERS (Cardiff)

The following were the other candidates:

Seymour Gilbert Barling, C.M.G. (United Hospitals, Birmingham),
Lennox Ross Broster, O.B.E. (Charing Cross)
Sir Lancelot Edward Barrington-Ward, K.C.V.O. (Great Ormond Street and Royal Northern)
John Bowman Hunter, M.C. (King's College)
Robert Milnes Walker (Royal Hospital, Wolverhampton)
Percival John Moir, M.C. (General Infirmary, Leeds)
Arthur Dickson Wright (St. Mary's)
Stanford Cade (Westminster)

In all 1,190 voted; in addition 20 votes were found to be for Major-Gen. Mitchner, Mr. Watson-Jones, and Prof. Paterson are all elected for the full period of eight years. Mr. Tudor Ed is elected as a substitute for seven years and Prof. Lambert Rogers as a substitute for two years.

Medical Notes in Parliament

APPEAL TRIBUNALS

Sir WALTER WOMERSLEY on June 24 moved the second reading of the Pensions Bill, which would give the right of appeal to all who had been refused pensions since the outbreak of war. He said wound cases received pensions almost automatically. The difficulties had arisen in dealing with disabilities which had been regarded as constitutional and not aggravated by war service. Such cases had been put before an independent medical expert with specialized knowledge of the disease concerned. That expert was nominated by the President of the Royal College of Surgeons or the President of the Royal College of Physicians. In every case pensions had been granted when these experts decided that the constitutional disease had not been aggravated by service in the Forces. The present Bill gave the right of appeal to all appellants who had been refused. There had been pensions appeal tribunals already for those who suffered disabilities arising out of the last war. All those who had been disposed of.

The principles in those tribunals set up after the last war had been satisfactory. He had modified the conditions of 1919 by which there was no pension if there had been serious negligence or misconduct. Provision had been introduced whereby a moderate pension could be granted. The House would agree that there should be an appeal against a reduced award as well as against a refusal of pension. In 1921 an appeal was brought into operation on the final assessment of the degree of a man's disability. He was providing in the Bill for that appeal, it would not be brought into operation at once because it would be against the interests of the man who might show deterioration over a period up to ten years. As after the war each tribunal would consist of three persons—in appeals relating to entitlement a lawyer, a doctor, and a layman; in appeals on assessment two doctors and a layman. He had the right to appoint doctors and had been told by the Secretary of the B.M.A. that there could not be a wide choice. He hoped these doctors would have experience of Service conditions, and that was a matter for the Lord Chancellor.

The right of appeal would extend to all to whom the Ministry had to award or refuse pensions. In the case of decisions on assessment issues, an appeal would require to be brought within 12 months of the notification of the decision. Proceedings of the tribunals would be regulated in England by the Lord Chancellor, in Scotland by the Lord President of the Court of Session, and in Northern Ireland by the Lord Chief Justice.

re tribunals would operate regionally in most cases in such centres as Liverpool, Manchester, Newcastle, Birmingham, and Cardiff. As time went on there would be an extension of tribunals so that no appellant need take a long journey.

Medical Views

Major MANNINGHAM BULLER said the tribunals would find themselves bound, as the Minister was, by the terms of the Royal Warrant. He thought the assistance of a medical assessor as all that was required on a tribunal and that it was unnecessary to provide that a doctor should have a vote. Dr. HADEN WEST said that while doctors were subject to prejudices, a doctor was always bound to be objective in his judgment on a patient. He thought the provisions of the Bill for obtaining evidence required strengthening. He knew of a case in 1939 where a civilian doctor had been ordered to examine a Territorial battalion of 900 men in two days. When women were admitted to the A.T.S. instructions were given that they were not to be completely examined. Therefore the records of those women were not complete. At Dunkirk, in Greece, Hong Kong, Malaya, Singapore, and to some extent in Libya there had been loss of medical records. It would be difficult to ascertain the condition of a man at a particular time. There were also cases of fraud. He knew a man with one glass eye who humbugged a medical officer to get into the Army. Sir HENRY MORRIS-JONES thought the Lord Chancellor was the right authority for setting up the tribunals. He hoped the Minister would accept an amendment providing that the qualification of seven years standing should be required for a medical member of a tribunal as for a barrister. Dr. MORGAN said medical men chosen in the way that had been announced would have no knowledge of judicial procedure, workmen's compensation, or social medicine. The list of men chosen by the B.M.A. had submitted to the Minister had been "vetted" by the Chief Medical Officer of the Ministry and by Lord Horder, two persons unqualified to decide. The Royal Colleges were purely examining bodies. The medical personnel at present available were not such as he would choose.

Mr. PALING, replying for the Government, said appellants could bring in any witness so long as there was no question of payment, but if the tribunal decided that specialist evidence should be brought in, the specialist would be paid. The Ministry had endeavoured to get the best people for the tribunals from the medical point of view.

The Bill was read a second time.

Postgraduate Course in Medical Radiology

Mr. MESSER asked Mr. Brown on June 10 whether the students of the only postgraduate course in medical radiology at present operating in this country had protested against the way it was conducted; and whether, in view of the urgent need for radiologists, in civil practice and the Services, he would consider exercising some measure of control over the British Institute of Radiology. Mr. ERNEST BROWN said the method of conducting this course was a matter for the university authorities and was not within his province. The British Institute of Radiology was not responsible for the course, but provided premises and other facilities for lectures arranged on behalf of London University through its special advisory board for the Diploma in Medical Radiology. His officers were discussing with this latter body the arrangements that could be made in the coming academic year to provide postgraduate instruction for suitable students to meet the requirements of civil hospitals and the Services.

Penicillin Clinical Trials Committee

Replying on June 10 to Major LYONS, Sir JOHN ANDERSON said the committee established by the Medical Research Council to organize clinical trials with penicillin was known as the Penicillin Clinical Trials Committee. Its members were: Prof. H. R. Dean (chairman), Dr. A. N. Drury, Prof. A. Fleming, Prof. H. W. Florey, Dr. Percival Hartley, Mr. R. Vaughan Hudson, Dr. C. M. Scott, Dr. J. W. Trevan, Prof. R. V. Christie (secretary), and Prof. L. P. Garrod (assistant secretary). Sir John added that there was consultation between this committee and the committee set up by the Minister of Supply (*Journal*, May 1, p. 553). The latter committee was primarily concerned with production, though it had to take clinical requirements into account. He was satisfied with the active attempts being made to manufacture penicillin. He thought its value had been established.

Tuberculosis Death Rate

In county and borough mental hospitals of England and Wales the death rates from all forms of tuberculosis per 1,000 resident males were: 1938, 4.92; 1939, 5.35; 1940, 7.52; 1941, 12.79; 1942, 13.06. For females they were: 1938, 3.77; 1939,

4.6; 1940, 5.68; 1941, 8.73; 1942, 9.01. For Scotland the comparable death rates were, for males, in 1938, 6.22 in mental hospitals and 2.66 in certified institutions. In 1939 the rates of males were 6.78 and 3.02 respectively; in 1940, 7.61 and 1.48; 1941, 9.11 and 3.43; 1942, 11.08 and 3.38. For females the rates in mental hospitals and certified institutions were: 1938, 6.14 and 1.18; 1939, 6.03 and 3.38; 1940, 6.33 and 1.11; 1941, 6.17 and 1.29; 1942, 9.23 and 4.32.

Hospital and Medical Services in Tunisia

On June 22 Sir FRANCIS FREMANTLE asked the Secretary of State for War if he would give some account of the arrangements and results of the hospital and medical services in Tunisia. Mr. ARTHUR HENDERSON circulated the following reply:

Detailed figures have not yet been received from North Africa, but all reports show that the medical arrangements made were highly successful. The medical services which formed part of the North African Force included certain new units which had not previously been employed on active service. Such, for example, were the field surgical units, which were attached either to main dressings stations of field ambulances or to casualty clearing stations. These units are in effect highly mobile operating teams, designed and fully equipped to function as such in forward areas. Associated with them were the field transfusion units, which have revolutionized the treatment of shock in the field. They conveyed and distributed the large quantities of blood and plasma used throughout the campaign, and together with the field surgical units played a large part in markedly reducing the mortality rate among casualties.

The evacuation of casualties on the whole followed lines which had been found successful in the past, but the evacuation was greatly accelerated by the transport facilities now available. These included ambulance cars, hospital trains improvised from rolling stock available locally, hospital ships, and aircraft. American aircraft evacuated over 16,000 British and American troops. The divisional medical units on occasion handled as many as 400 to 600 casualties a day. The less urgent cases were sent direct to casualty clearing stations, the cases in need of blood transfusion and resuscitation were retained, and the cases requiring immediate operations were dealt with by the field surgical units.

The hospitals in general used to accommodate casualties were general hospitals of 200, 600, and 1,200 beds. The speed with which they opened on new sites and accepted casualties was one of the outstanding features of the campaign from the medical point of view. These hospitals were mainly accommodated in tents, although the administrative parts were often in buildings. Hospitals were provided with the necessary specialist personnel and equipment to deal with cases of all types, including surgical, medical, laryngological, ophthalmological, dermatological, psychiatric, neurosurgical, and maxillo-facial cases. Special depots were provided to care for convalescents and for those who were lightly wounded, and to ensure that they were soon fit to return to duty. The general health of the troops and their standard of hygiene remained good throughout the campaign. This was due, at least in part, to the improved education of all ranks and to the better understanding by all of the problems involved.

Pneumoconiosis, Etc.—Schemes were presented to Parliament on June 29 entitled the Coal Mining Industry (Pneumoconiosis) Compensation Scheme, 1943; the Pneumoconiosis (Benefit) Scheme, 1943, and the Silicosis and Asbestosis (Medical Arrangements) Amendment Scheme, 1943; and also the Pneumoconiosis (Medical Fees) Regulations, 1943.

Medical News

Prof. Semon Sarkisov, Vice-President of the Scientific Medical Council of the U.S.S.R. and Director of the Institute of the Brain, Moscow, will speak on Soviet medical workers in the present war at the Royal Society of Medicine, London, on Thursday, July 15, at 5.30 p.m. Visitors will be welcome.

The Nuffield Ulster Provident Association, Ltd., has been launched under guarantee of the Nuffield Provident Fund. The benefits and premiums are identical with those of the Nuffield Provident Schemes in Great Britain and membership is interchangeable on transfer of a member to another locality where such a scheme is in force. The affairs of N.U.P.A., Ltd., are in charge of an elected Council of 16 members under the chairmanship of Mr. D. Lindsay Keir, Vice-Chancellor of Queen's University, Belfast. A survey of the hospital services of Northern Ireland is at present being carried out for the Nuffield Regional Hospitals Council by Lieut.-General Sir W. P. MacArthur, Dr. Duncan G. Leys, and Dr. Stanley Barnes.

The British Association of Scientific Workers has arranged a meeting on Sunday, July 11, at 7 p.m., in the Lecture Theatre of Birkbeck College, Fetter Lane, E.C., in order to demonstrate the importance of the joint efforts of the scientists of the British Commonwealth and the U.S.S.R. It is timed to coincide with a meeting of Soviet scientists in Moscow, and greetings will be exchanged. Chairman, Sir Robert Watson-Watt, F.R.S.; speakers, Prof. J. D. Bernal, F.R.S., Mr. J. G. Crowther, Prof. S. A. Sarkisov, and Sir Alfred Webb-Johnson, P.R.C.S.

Sir StClair Thomson, who died on Jan. 29, left £149,675. Among other bequests are £1,000 each to the Royal Medical Benevolent Fund and the Royal Society of Medicine; £500 each to the Royal College of Physicians, the Royal College of Surgeons, and Epsom College-Foundation; and, on the death of his sisters, £4,000 to the Royal Society of Medicine, and £500 each to the Royal College of Physicians and Epsom College Foundation.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* the downward trend of infectious diseases continues: scarlet fever by 280, measles by 252, whooping-cough by 145, diphtheria by 67, and acute pneumonia by 50 cases. Notifications of dysentery were up by 37, of cerebrospinal fever by 9, and of paratyphoid by 6.

The 540 notifications of diphtheria establishes a new low record for this disease. The incidence is unusually large in the North, and the counties of Warwickshire, Lancashire, Yorks West Riding, and Durham contributed 265 cases—practically half of the total for the country.

The fall in incidence of scarlet fever was steepest in Yorks West Riding by 64, London by 51, and in Kent by 38 cases. The only large variation in whooping-cough was the drop of 104 cases in Lancashire.

There were 101 fewer notifications of measles in Staffordshire, 68 in Surrey, 63 in Northamptonshire, and 61 fewer in Buckinghamshire. Among the counties with an increased incidence the most notable were Kent, with 129 additional cases distributed generally, and Norfolk, with an increase of 58, mainly due to a local outbreak in Wayland R.D.

For the third week running an increase has been recorded for dysentery. The fresh outbreaks during the week were in Essex, Saffron Walden U.D., 17; in Berkshire, New Windsor M.B., 10; Cornwall, Bodmin M.B., 8; Somerset, Long Ashton R.D., 7; Lincolnshire, Scunthorpe M.B., 6; 8 further cases were reported from the outbreak in Gloucestershire, Bristol C.B., and 15 more from the two outbreaks in Warwickshire, Birmingham C.B. 9 and Warwick R.D. 6.

Of the 7 cases of typhoid fever 4 occurred in Surrey, Richmond C.B.

In *Scotland* the fall in the incidence of infectious diseases was general, but notifications of scarlet fever were up by 20. Although 79 fewer cases of dysentery were recorded, the disease remains at a fairly high level, with 56 cases (Edinburgh 14, Glasgow 11).

In *Eire* there were slight rises in the notifications of diphtheria, 14, and of scarlet fever, 7. Both diseases are widespread, the largest centres of infection being Dublin C.B., with 18 cases of diphtheria, and Co. Limerick, Newcastle R.D., with 9 cases of scarlet fever.

Quarterly Return for Eire

The birth rate during the March quarter was 22.7 per 1,000, was 3.3 above the rate for the first quarter of 1942. Infant mortality was 94 per 1,000 births, this being 14 above the rate for the corresponding quarter of 1942. The general death rate was 17.1 per 1,000, being 0.8 above the rate for the first quarter of the preceding year. Deaths from the principal epidemic diseases yielded a rate of 0.7 per 1,000, compared with 0.3 in the first quarter of 1942. Deaths from pulmonary tuberculosis numbered 959, compared with 904, 832, 824, 690, and 673 in the first quarters of the five preceding years: 224 deaths were attributed to other forms of tuberculosis, the same number as that recorded for the preceding year but slightly above the totals for the first quarters of 1939-41. The other most notable increases were those of whooping-cough, diphtheria, and diarrhoea and enteritis under 2 years, for which 93, 94, and 277 deaths were recorded with the averages of 43, 69, and 137 for the five preceding first quarters.

The Week Ending June 26

The notifications of infectious diseases in *England and Wales* during the week included: scarlet fever 1,680, whooping-cough 2,330, diphtheria 582, measles 5,774, acute pneumonia 553, cerebrospinal fever 64, dysentery 107, paratyphoid fever 11, typhoid fever 11.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended June 26.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1943					1942 (Corresponding Week)

* Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

† Includes puerperal fever for England and Wales and Eire.

‡ Owing to evacuation schemes and other movements of population, birth and death rates for Northern Ireland are no longer available.

Letters, Notes, and Answers

communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Secretary of the Journal Board, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS if reprints are required, as proof's are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be sent to the Secretary.

TELEPHONE: No. 1—B.M.A. and B.M.J.: EUSTON 2111.
LITHOGRAPHIC ADDRESSES—EDITOR, *Attilage Westcent*, London; SECRETARY, *Medisecra Westcent*, London.
M.A. SCOTTISH OFFICE: 7, Drumshrub Gardens, Edinburgh.

ANY QUESTIONS?

Treatment of Unresolved Pneumonia

Q.—What measures may be adopted to hasten the resolution of an unresolved pneumonia?

A.—(1) Make sure that the condition is one of unresolved pneumonia and not of empyema. If there is any doubt—and there often is—explore the chest. (2) Do not give any more sulphonamide drugs. (3) Apply heat, either in the form of cataplasma kaolin, renewed every 12 hours, or, if possible, use short-wave therapy. (4) Encourage the patient to take deep breaths to expand the lung for a few minutes every hour. (5) If the general condition of the patient is bad, the temperature low, and the pulse unduly frequent, cardiac and respiratory stimulants are of the greatest importance. Nikethamide 1 c.c.m. or leptazol 1 c.c.m. should be injected subcutaneously three or four times a day. (6) In asthenic cases in which there is no leucocytosis dium nucleate, 0.1 g. in 2 c.c.m., should be injected intramuscularly twice daily. (7) Antiserum or vaccine treatment is not recommended.

Dystocia Dystrophia

Q.—Forty-five days after the expected date of birth a Caesarean section was performed on a woman aged 32, and a baby was delivered weighing 12 lb. 8 oz., having great development of adipose tissue, articulary about the upper eyelids. After operation no milk was secreted, and the uterus did not retract very well. The baby died 9 hours after birth, the post-mortem findings being negative. No ailed-eye changes were observed in the placenta. The mother made an uninterupted recovery. Previous to Caesarean section, castor oil and quinine had been given in fruitless attempts to start labour, which even at the time of operation showed no sign of approach. Uterine had appeared in the urine six weeks before the expected date of birth. This cleared up with rest in bed, dieting, and laxatives, but there were recurrences throughout the pregnancy—never more than a trace. Blood pressure varied from 135 to 162 systolic and 0 to 85 diastolic. She once had slight haziness of vision but no usual retinal changes were seen. The pelvic measurements were transverse $4\frac{1}{2}$ in. and antero-posterior $4\frac{1}{2}$ in. Five weeks before the expected date of birth the foetal position was L.O.A., and the head, though not engaged as firmly as one expects in a primipara, was easily palpable and could be pushed into the pelvis. What treatment should be adopted in any future pregnancy? Should Caesarean section be done at term? Was the prolongation of pregnancy due to lack of pituitary? The mother began to menstruate at the age of 15 and had a 32- to 35-day interval.

A.—This case presents in a gross degree the features of a syndrome which in recent years has been described in American literature under the term "dystocia dystrophia." Patients presenting this syndrome are usually of heavy build, are relatively infertile, and are especially prone to the late toxæmias of pregnancy. The uterus is insensitive, formation of the lower segment is delayed or disturbed, and the presenting part remains high. Post-mature onset of labour is common, and the labour itself is characterized by incoordinate or feeble uterine contractions with slow dilatation of the cervix. Faults in the shape or size of the bony pelvis are often present, but even in the absence of these the labour is long and difficult and posterior rotation or transverse arrest of the foetal head is common. Foetal mortality is high. The syndrome, in varying degrees, is not uncommon, and as its name implies is believed to be the result of disturbed pituitary function, although definite proof is lacking. No special treatment is of any real value during pregnancy, although the administration of oestrogens in the last few weeks may improve uterine tone and sensitivity. Medical induction usually fails, and quinine is contraindicated in the presence of toxæmia. Mechanical induction should be avoided if the presenting part is high. Treatment in labour should follow the ordinary rules of obstetrics, and should in the early stages be conservative, but if the labour is not progressing satisfactorily then lower-segment Caesarean section is preferred.

able to any difficult vaginal procedure. In the particular case in question the treatment of any subsequent pregnancy should be by Caesarean section one or two weeks before term, or earlier if signs of toxæmia develop and the size of the baby is sufficient to ensure it good prospects for survival. The risks of faulty retraction of the uterus and post-partum haemorrhage would be minimized by operating under local anaesthesia.

Vitamin Requirements

Q.—What are the current accepted daily adult requirements of the vitamins A, B, C, D, E, and K, expressed in milligrammes and I.U.? How do these requirements vary with age and/or body weight?

A.—The answer to this question is best given in tabular form.

Age	A		B		C		D		E		K	
	I.U.	Mg.	I.U.	Mg.	I.U.	Mg.	I.U.	Mg. of 1 lb.	I.U.	Mg.	I.U.	Mg.
Adult	5,000		600	1.8	1,500	75	300-7-600-2	0.0075-0.015				
Under 1 year	1,500		133	0.4	600	30	400-800	0.01-0.02				
1-3 years	2,000		200	0.6	700	35	400-800	0.01-0.02				
4-6	2,500		266	0.8	1,000	50						
7-9	3,000		333	1.0	1,200	60	3,500	0.0375				
10-12	4,000		400	1.2	1,500	75	weekly	weekly				
Girls 13-15 years	5,000		500	1.5	1,500	75	300-7	0.0075				
16-20	5,000		500	1.5	1,500	75	600-7	0.015				
Boys 13-15	5,000		500	1.5	1,500	75						
16-20	5,000		666	2.0	2,000	100						

* It is not certain whether adolescents and adults need an extraneous supply of vitamin D. Enough may be made under the skin by the action of light.

Requirements and Body Weight: Vitamin A.—Requirements directly proportional to body weight and age. Vitamin B₁.—Requirements depend on caloric intake and not body weight. Vitamin C.—Requirements depend upon degree of body metabolism rather than on actual body weight—e.g. a small person suffering from pyrexia will need more than a larger person who is afebrile. Vitamin D.—No apparent relation between body weight and requirements.

Complications of Diverticulitis

Q.—A patient had diverticulitis of the pelvic colon 10 years ago with perforation into the bladder. Colostomy was followed by immediate "functional" closing of the fistula, but stent was passed occasionally per urethram. A gradually increasing amount of pus (now about 1 oz. daily) is passed, chiefly from lower opening (anus) of lower bowel, latterly becoming bloody. Examination shows *B. coli*, staphylococci, and non-haemolytic streptococci in the pus. There are no cellular elements suggestive of malignancy. Surgical intervention is not advised. Will any palliative treatment diminish the pus—which may eventually enter the bladder? Sulphonamides in moderate doses for short periods are ineffective. Are any of the flavins advisable locally? If so, in what form and concentration?

A.—The pus in this case is probably derived from two sources—one a diverticular abscess and the other a secondary proctitis which is kept up by the constant drainage of pus into the rectum. Although the effect of courses of sulphonamides has not been spectacular, it is advised that these be repeated at intervals (with the usual check on the white cells), ringing the changes on the various products, owing to their specificity of action. Penicillin is not yet generally available, but would be worthy of trial when it becomes so. Flushing the lower segment of the bowel regularly would be advisable, but it is doubtful whether the antiseptic lotions (e.g. 1/1000 acriflavine) have much advantage over plain saline.

Night Sweats and Anxiety

Q.—Is anything definite known of the underlying aetiology of night sweats? A patient of mine (aged 43) has been troubled with these every night for about six months. He is quite healthy apart from duodenal ulceration. He wakes suddenly about an hour and a half after falling asleep to find himself sweating all over. Immediately he wakes the sweating stops. It is not that he has too many clothes on the bed. He has been troubled similarly at times within the past few years, but the periods were appreciably shorter (7 to 21 days). I can rely on his story, as he is a well-educated intelligent man. He tells me that since boyhood he has been an easy sweater, perspiring profusely when playing games, dancing, etc. All the conditions with which night sweats are associated have been excluded. Incidentally, I have seen this condition in men about 40 years old fairly often in the past two years, though the condition did not persist so long. Is there any treatment of help?

A.—Little is known of the pathogenesis of night sweats. As the questioner says, the complaint is not rare, and slighter disturbances of the same type are commonly met with. Night sweats have been regarded as a cardinal symptom of the anxiety neurosis. In a patient

therefore who is already suffering from one psychosomatic disease, it is most probable that the night sweats are to be explained by a similar mechanism. Inquiry should obviously be made for any sources of anxiety which may be playing a part in the aetiology of both the duodenal ulcer and the sweating. It would also be reasonable to try a zinc oxide and belladonna pill and one of the shorter-acting barbiturates, though the response to treatment is usually not good.

Immunity after Virus Infection

Q.—Is the solid immunity which so often results from virus infection due to persistent infection? Is it not true that this persistence of infection may actually be detrimental in that it renders the individual more susceptible to reinfection?

A.—It is known that under experimental conditions clinical recovery from a virus infection may not represent a complete recovery; a residual infection is left which may persist for a considerable time. Such a residual infection would presumably be kept going by the occasional breakdown of an infected cell with the liberation of virus and the infection of a few new cells. The repeated antigenic stimuli so provided would maintain a high antibody level and so a high degree of immunity. One is tempted therefore to conclude that the solid and lasting immunity which is left by so many virus infections is the direct result of persistent infection. The life-long duration of the immunity which is left after recovery from diseases like small-pox or yellow fever makes some hesitate to accept this view because they think it unlikely that the infection with these viruses would persist so long. There is no evidence that persistence of a virus infection renders an individual more prone to reinfection. An apparent exception such as herpes is apparent only since—with the exception of the primary infection, which in the majority of cases occurs in the early years of life—the virus responsible for the attack of herpes is carried by the sufferer.

Allergy to Bee Stings

Q.—What form of allergy is shown in the following case? A man aged 30 was stung by a bee on the right eyebrow in May, 1942. The swelling subsided in 48 hours. In August, 1942, he was stung again, this time on the first finger, left hand. The right eyebrow as well as the finger were swollen, both subsiding in 48 hours. In May, 1943, he was stung on the left side of the neck. The whole of the left arm was affected, and also the right eyebrow and the neck. All subsided in 48 hours.

A.—Two characteristic phenomena of allergy are exemplified in the experiences outlined.

(a) Persons engaged in certain occupations become sensitized to substances they handle, bees differing from other hazards in that in their case the allergen is injected into the patient and not just applied to the skin or inhaled by the mucous membranes, and so the reaction tends to be primarily of an angioneurotic oedema type. With each sting the patient tends to become a little more sensitive, and with sufficient bites acute allergic shock or even sudden death may occur. The original sensitization in a non-allergic person usually follows a massive exposure or some period of ill-health, worry, or fatigue, conditions in which the body's supply of adrenaline is low. If the patient is already allergic to other substances or a member of a very allergic family, severe reactions arise after fewer exposures and the period of low adrenaline production may not be essential.

(b) If serum is prepared, say, from a person allergic to egg, and injected into a site in the skin of a non-allergic person, and the non-allergic person either eats egg or has egg injected parenterally, or a site in the skin is tested with egg, a localized wheal appears, showing that localization of sensitization does occur even in a non-allergic person. If an allergic person gives a large local reaction to a skin test, say, for dust or pollen, and a course of desensitizing injections is begun, the sites of the previous skin tests frequently swell and itch with each injection, and often each of the sites of his previous injections as well, showing that a greater local sensitivity at certain points is maintained. So in this bee case. Each site of a sting is more highly allergic than other sites, whilst the body develops its general sensitization and so reacts more obviously with each dose of the allergen.

Preventive treatment consists in giving up the bees or in desensitization. For desensitization bee toxin can be used in gradually increasing doses with additions of small amounts of adrenaline to each dose; or a whole bee extract (obtainable from Messrs. C. L. Bencard Ltd., 30rgate Hall, Dereham, Norfolk) can be employed, as experiments have shown that the whole bee extract protects against bees, wasps, and ants.

Invasion of Earwigs

Q.—What is the most effective insecticide with which to combat an invasion of earwigs?

A.—Invasions of earwigs in houses seem to be more common in recent years, especially in new housing estates. They favour damp situations, so they are frequently found in bathrooms and recently decorated rooms. One way of discouraging them therefore is to

dry out the house so far as is possible. The grounds about the house should be inspected, and rubbish or any articles giving cover to insects should be removed, as well as kitchen refuse, which should be provided them with food. It is difficult to suggest a good insecticide at present owing to demands for more serious pests. If the infestation is very heavy the best measure is fumigation. A light infestation can be cleared up with a good domestic spray (of which the several on the market) plus extermination of the earwigs in the garden. For the latter the following poison bait has proved effective in extensive American trials: wheat bran (or dried apple powder) 12 parts; sodium fluosilicate (or sodium fluoride) 1 part; fish oil (or cod-liver, rape seed, or coconut oil) 2 parts. The bran and fish oil are mixed together and the oil added afterwards; no water should be added. Strew the bait evenly and thinly about the neighbourhood, especially at the base of walls, fences, trees, and telegraph poles.

Toxic Properties of Paradichlorobenzene

Q.—Paradichlorobenzene is much used to keep away the clothes moth. The other day I was in a house where the airing cupboard contained the hot-water cylinder. The winter blankets were hanging here, and there was a liberal sprinkling of the above-named substance, which was vaporized by the heat of the cylinder, and a powerful odour permeated the adjoining bedroom. What would be the probable toxic effects of this vapour?

A.—While the effects of pure paradichlorobenzene have not been closely investigated, they are regarded as similar to, but more than, those of orthodichlorobenzene, and commercial varieties of these compounds contain the other. The acute effects of paradichlorobenzene are fairly strong narcosis and pronounced irritation of the liver and kidneys; concentrations of 0.1% were lethal to guinea-pigs after 20 hours. According to Solomon several workers exposed to this vapour for one or two years developed toxic hepatitis and cataract.

LETTERS, NOTES, ETC.

Sulphanilamide and Mumps

Dr. J. Lowy (London, N.W.1) writes: Many practitioners found that sulphanilamide is highly effective in the treatment of mumps. In my opinion its use should be limited to adults because of its powerful effect, which hinders the body from gaining immunity but protects adults from troublesome complications. On the other hand, complications are very rare in children, and they gain long immunity if mumps is treated by the customary method not at all. In Czechoslovakia I observed how effective treatment hindered the development of immunity when children treated with diphtheria antitoxin contracted diphtheria in three successive years.

Shortened Puerperium

Dr. G. C. TAYLOR (Peterhead) writes: Mr. Denys Neal (May 22, p. 644) reopens a subject which is of great importance. No hard-and-fast rule can be laid down as to the length of the puerperium, but present-day fashion prescribes longer rest than is necessary. I have found, as many others have before me, that leg and abdominal exercises in bed from the first day of the puerperium enable the patient to get up usually from the 8th to 10th day without much difficulty. Many get up to work from the day onward, although this action is usually concealed from the doctor. These leg exercises are the best preventive of that distressing malady white leg. A few weeks ago a 53-year-old woman from a rural district in Scotland consulted me regarding a minor degree of prolapse of the uterus. The patient was very bright and full of life and spirits. On inquiry into her history she stated that her mother, now 75 years of age and fit for daily work in the field, had borne twenty-two children and never spent more than two or four hours in bed after labour. The patient, not to be outdone by her mother, had produced twenty-three children, and again two or four hours was her period of rest. She told me that she always got up on the 2nd day and performed all her household duties besides some heavy outdoor tasks. It is true that 25% of the progeny do not reach adult life, but that is beside the point. The patient apparently none the worse for her "ordeals." The history of the case prompts the question: "Are we right in insisting on the 14 days' rest after normal labour?"

Theophylline for Asthma

Dr. J. F. LANG (Bathgate) writes: In your annotation on theophylline for asthma (June 12, p. 731) you mention the treatment of asthma with this drug by Hermann and Aynesworth, as if their observations were the first made on this treatment. I had mentioned the drug at a meeting of the B.M.A. in Glasgow in 1911 and a note of some of my cases was printed in *Clinical Excerpt* (Jan., 1931). It may be worth while for practitioners to remember while treating intractable cases of whooping-cough where cyanosis and dyspnoea are present, that very small doses of this drug are sometimes effectual for the relief of these distressing symptoms.

[WITH PHOTOGRAPHURE PLATE]

Recent investigation (Kneeland and Smetana, 1940; Longcope, 1940; Blake *et al.*, 1942; Reimann *et al.*, 1942) indicates that the term "atypical primary pneumonia" embraces a clinical group of closely related infectious diseases, in certain cases of which viruses have been definitely established as the aetiological agents. In other instances where no virus has yet been isolated the pathological and clinical evidence suggests a virus infection. Such viruses hitherto isolated appear to be antigenically related to, although not identical with, the viruses of psittacosis, lymphocytic choriomeningitis, and lymphogranuloma venereum, all of which can produce meningitis as well as pneumonia in man or animal. Moreover, Smadel and his co-workers (1942) report two cases of lymphocytic choriomeningitis, in both of which extensive pneumonitis was found at necropsy. The lungs closely resembled those described in the few available pathological descriptions of atypical pneumonia.

Scadding (1937) reported a case of encephalitis and "disseminated focal pneumonia" (atypical pneumonia) in a patient previously treated in hospital for atypical pneumonia. The presenting syndrome was that of laryngeal paralysis. At necropsy the medulla, pons, and midbrain contained small areas of softening and haemorrhage; microscopically, perivascular "cuffing" and focal degeneration of nerve cells were prominent. In two other adult cases in which the brain was examined (Longcope, 1940) no evidence of encephalitis was found. In nine necropsies on infants with "primary virus pneumonitis" (Adams, 1941) no clinical or pathological evidence of encephalitis was discovered.

Reimann (1938) reported a case of atypical pneumonia in which positive Kernig and Babinski reflexes and ankle clonus could be elicited. The patient was comatose at intervals, the pupils sluggish and dilated; strabismus was noted and the neck was slightly rigid. Spinal fluid pressure was 220 mm.; the cell count varied between 220 and 350, with 78 to 91% polymorphonuclear cells; total protein was 74 mg. per 100 c.cm. Attempts to isolate a virus from the spinal fluid were unsuccessful. Complete recovery took place.

Hein (1943) reported two cases of atypical pneumonia showing clinical and laboratory evidence of meningo-encephalitis. One was that of a 23-year-old soldier who developed photophobia, stiff neck, and a positive Kernig sign on the fifth day of his illness. Cerebrospinal fluid contained 380 cells (77% polymorphs, 23% lymphocytes); Pandy's reaction was positive, sugar content raised, chlorides low; cultures were sterile. Temperature eventually fell to normal and the chest became clear, but the cerebrospinal fluid continued to have a high lymphocyte count for some time. Eventual recovery was

complete. The second case was that of a 34-year-old soldier with a maculo-papular rash who on the fourth day in hospital complained of headache, became confused, and developed a stiff neck. Cerebrospinal fluid contained 26 cells, all lymphocytes; Pandy's reaction was positive, sugar and chlorides normal. In this case, also, clinical improvement preceded clearing of the cerebrospinal fluid.

Case Report

Corporal A., aged 20, was admitted to an American Army hospital in England on Feb. 1, 1943. His illness had begun the previous day with cough, soreness in the throat on coughing, fever, nasal obstruction, moderate headache, and some aching pains in the chest and arms. Except for frequent attacks of tonsillitis during the previous year his past history was negative. The family history was also non-contributory.

On admission his temperature was 101.2°, pulse 95, and respirations 20. He appeared moderately prostrated; face and neck were flushed; eyes watery and injected. The right naris was partially obstructed, and a scant nasal discharge was present. The pharynx and posterior half of the palate were diffusely reddened; tonsils were moderately enlarged. The neck was not stiff. Lungs were clear and the rest of the examination was essentially negative.

Laboratory findings were as follows: Urine: Negative except for trace of albumin in terminal specimen. Blood count: Feb. 2, Hb 90%, R.B.C. 4,250,000, W.B.C. 5,700—79% polymorphs; Feb. 6, W.B.C. 8,700—97% polymorphs; Feb. 7, Hb 90%, R.B.C. 4,450,000, W.B.C. 6,550—90% polymorphs; Feb. 10, Hb 103%, R.B.C. 4,040,000, W.B.C. 6,900—85% polymorphs. Sedimentation rate: Feb. 3, 10 mm., Feb. 5, 22 mm. per hour. Blood cultures on Feb. 4, 7, and 10 were negative. Throat cultures on Feb. 2 gave *Staph. albus*, and sputum cultures on Feb. 5 and 6 showed *Staph. albus* and pneumococcus. On Feb. 11 the spinal fluid contained 8 polymorphs and 68 lymphocytes per c.mm.; culture was sterile.

Radiographs of the chest on Feb. 8 revealed a large area of consolidation in the right lower lung field; both lung fields were filled with numerous small soft shadows.

Clinical Course (see Chart)

On admission the patient was placed on sulphadiazine, 1 g. every four hours by mouth. Despite this the temperature rose to 104° each afternoon, and he was moderately toxic. At times slight cyanosis was observed. On his fifth day in hospital rales were heard in the left chest. Because of increasing dyspnoea and cyanosis, oxygen was administered, with immediate disappearance of cyanosis. Moderate amounts of bloody sputum were expectorated. Sticky, bubbling, and crepitant rales and wheezes became audible throughout both lungs; inspiratory dilatation of the alae nasi and expiratory grunting were observed. On the sixth day in hospital sulphadiazine was stopped and the patient was transfused from another patient three weeks convalescent from severe atypical pneumonia. After 125 c.cm. of blood had been given the procedure was halted because of restlessness and increased dyspnoea. Five hours later the temperature had dropped sharply to normal, and the patient seemed greatly improved. The next day he complained considerably of generalized headache; fever recurred in the evening associated with considerable abdominal distension, which was relieved by rectal tube, turpentine stupes, and

posterior pituitary extract. Chemotherapy was resumed, with two 4-g. intravenous doses of sodium sulphathiazole; a blood level of 2.6 mg. per 100 c.cm. was obtained. The oral dose of sulphadiazine was doubled to 2 g. every four hours, and the blood level rose to 12.5 mg. without clinical improvement. Dullness and bronchial breathing appeared in the right axilla. Although dyspnoea was diminished somewhat, the pulse rose from 120 to 140-150 and became thready at intervals. The patient became progressively less

membrane-like layer of fibrinoid material and occasionally embedded in typical fibrin strands. The mononuclear cells predominated in most fields, but were about equalled by the polymorphonuclears in a few areas. Much of the alveolar epithelium had been stripped from the lining surfaces, and formed part, at least, of a mononuclear-type cells. The remainder occurred as a desquamated layer of cuboidal, columnar, or somewhat spheroidal cells. Occasional larger mononuclear cells with hyperchromatic nuclei

responsive; moderate neck rigidity was noted, and motion of the head evidently caused pain. Fluids, sodium chloride, and glucose were given orally, by infusion, hypodermoclysis, and per rectum. The loss of panniculus and muscular atrophy were marked and progressive. Digitalization with 18 cat units of digitalis intramuscularly appeared to slow and strengthen the pulse. A second transfusion of 10 c.cm., using the blood of a two-weeks-convalescent who had had moderately severe atypical pneumonia, was given on the tenth day without noticeable effect. On the eleventh day the patient could no longer swallow sulphadiazine tablets; and chemotherapy, having failed to produce any improvement, was discontinued. The pupils came widely dilated, the skin clammy, cyanotic, and mottled, and the eyes glazed. A third transfusion of 250 c.cm. of blood from a two-weeks-convalescent moderately severe case improved the patient's general condition somewhat, but during the night the pulse came irregular and thready, and respiration stopped. After intratracheal caffeine respiration was restored, and a large mucous plug was extracted from the pharynx. Three hours later respiration again stopped and further stimulation was unsuccessful; the heart ceased shortly thereafter. The patient died on the thirteenth day in hospital.

Necropsy Findings

Post-mortem examination was performed three hours after death. The body was well developed and moderately well nourished. There was slight rigidity, and livor of transient type was present in the dependent parts. Pupils were equal, 7 mm in diameter. There was no discharge from ears, nose, or mouth. The thorax was symmetrical and the abdomen flat. Extremities revealed marked cyanosis. Superficial vessels and lymph nodes were normal.

Lungs.—The right lung weighed 1,260 g., and its size and position were usual. It appeared uniformly bright red. The entire lung was firmer than normal, the most notable increase in consistency being present in the middle and lower lobes. The pleural surfaces were smooth and glistening, with the exception of a small area on the antero-lateral surface of the lung 3 cm. from the apex. Here there were several fine adhesive bands with minimal roughening. The surfaces of lung revealed intense bright-red colour of the parenchyma with moderate increase in moisture. Consolidation was lobular and confluent lobular type. Several small areas of emphysema were present throughout the upper lobe. In the periphery of the upper lobe beneath the pleural adhesions several small areas of necrosis, measuring 1.5 mm. in diameter and appearing much like miliary seedlings, were observed. Yellow muco-purulent exudate issued from the small bronchi, and the larger air passages were filled with this secretion to within 3 cm. of the tracheal bifurcation. The bronchial walls were swollen and congested. Hilum nodes were slightly enlarged and firm. The left lung weighed 1,010 g. The upper lobe was red, moist, and similar in appearance to the right lung. The lower lobe was nodular in appearance, and revealed marked increase in consistency. The cut surface of both lobes was intensely red, and the muco-purulent exudate was present throughout the bronchial tree. The hilum nodes were enlarged and firm.

Microscopical Examination of Lungs.—The alveoli contained varying quantities of exudate consisting of large numbers of mononuclear (macrophage type) and polymorphonuclears lying within a

abundant cytoplasm were seen contiguous with the layer of alveolar epithelial cells. No inclusion bodies were seen in these cells. Zones of interalveolar haemorrhage were present. Bronchioles presented varying degrees of ulceration and deposition of abundant fibrinoid material. The remaining epithelium was of stratified variety. The bronchial walls showed extensive lymphocytic infiltration, plasma cells, polymorphs, and some eosinophils. The pleura revealed some engorged vessels but no exudate. One section showed a nodular zone of fibrosis with a central area of caseation and coagulation necrosis. Rare foreign-body giant cells were present. No acid-fast bacilli were demonstrated with Verhoeff's acid-fast stain.

The heart, aorta, and vessels revealed no pathological changes. The spleen weighed 252 g. and measured 13.5 by 6 by 3 cm. It was red-grey in colour. The capsule stripped with slightly increased difficulty. The cut surface was deep-red and moist. Markings were vague, and pulp scraped slightly. Microscopical examination revealed areas of haemorrhage into the pulp with moderate increase in polymorphs. The liver, pancreas, and adrenals were normal. Gastro-intestinal and genito-urinary tracts were normal.

The Brain.—The dura did not appear swollen. Vessels were of average size. The leptomeninges showed no gross pathology. Spinal fluid was clear and there was no exudate. Convulsions and signs appeared normal. The consistency of the brain was slightly softer than usual. On sectioning the cerebrum numerous pinhead-sized areas of dark-brown pigmentation were noted in grey and white matter. It could not be determined, by gross examination, whether these were small areas of haemorrhage or inflammation. The cerebellum, pons, and medulla were normal.

Microscopical Examination of the Brain.—This revealed frequent foci of increased cellularity in white matter of sections from parietal, temporal, and occipital lobes, from the region of the basal ganglia, paraventricular (III, IV) tissue, and cerebellum. These were located in juxtaposition to or surrounding small vessels, and were usually associated with a ring of peripheral haemorrhage. Cells forming these foci were astrocytes and microglia, with predominance of the former, and occurred in a density approximately ten times that of the regional white matter. There was slight phagocytosis of erythrocytes in a few areas. The grey matter presented occasional large swollen, diffusely staining cells. The ependyma of all ventricles was negative. Leptomeninges presented areas of lymphocytic perivascular infiltration in sections from parietal and temporal zones. Vessels of both leptomeninges and of brain parenchyma were considerably engorged, and scattered "ring" haemorrhages without focal cell proliferation were present in grey and white matter.

Diagnosis

Lungs.—(1) Pneumonia—primary, atypical, of lobular and confluent lobular type—with ulcerative bronchitis and membranous interstitial pneumonitis. (2) Tuberculosis—minimal, old, foci inactive.

Brain.—Encephalitis—acute. (Encephalitis is used in the general sense and not necessarily as the designation of direct reaction to a specific infectious agent. The severity of the reaction and doubt a

purely degenerative character of the lesions make this term preferable to encephalopathy or encephalosis.)

Bacteriology.—Cultures from brain, heart, and right and left lung all sterile at the end of 72 hours.

Studies.—The following-virus studies were negative: (1) Lungs were inoculated into twelve mice, one rabbit, and one guinea-intranasally by Major T. F. McNair Scott, M.C., U.S.A. glycerinated lung tissues were inoculated into cotton-rats and reported as non-effective by Dr. C. H. Andrewes, National Research Institute, Hampstead. (3) Brain tissues were inoculated by McNair Scott intracerebrally into six mice, one rabbit, one pig, and one hamster. The rabbit died with encephalitozoon on the fifth day after inoculation.

Discussion

Initial descriptions of cases of atypical pneumonia often stress the frequency and severity of headaches. Thus out of 45 cases we have observed at one hospital, 41 (47%) complained of headache—14 mild, 6 moderately severe, and 21 severe. Headache is usually frontal or ocular, though it may be realized in severe cases. It occurs as a rule at the onset of the disease, and is rarely absent in severe cases of atypical pneumonia. Coughing increases the headache considerably. Including the case reported above—the sole fatality in our series—lumbar puncture was performed in only one other case. This was one with severe frontal headache but no signs of meningitis or encephalitis; spinal fluid was normal. We have under observation another patient who, during a previous attack of atypical pneumonia, had severe headache and positive Kernig, Chaddock, and Oppenheim reflexes. Unfortunately lumbar puncture was not performed. Recovery was complete. Apparently our patient died of encephalitis rather than of pneumonia, since dyspnoea and rales became less in the last days and abdominal distension disappeared. Indications of central nervous system involvement appeared abruptly on sixth day in hospital, when the patient began to complain of severe headache. At the same time the temperature rose and neck rigidity was noticed. This encephalitis must be distinguished from a post-infectious encephalitis, which is characterized histologically by patchy areas of demyelination. These were not a prominent feature in this case, in which brain lesions resembled more closely those of epidemic encephalitis.

In our case of atypical pneumonia was due to a virus it might be conjectured that, as with analogous virus infections, antibodies would develop in the blood of convalescents, and that transfusions of convalescent blood might favourably affect the course of the disease. Flexner and Garon (1943) report three cases in which small transfusions from convalescents were administered. Two of these patients, very ill at the time of transfusion, eventually died; the third, who had had a sustained temperature of about 103°, became afebrile within 24 hours and remained well. Kneeland (personal communication) has tried use of two unpublished cases in which convalescent blood was employed. In one case a husband, three weeks convalescent, gave 500 c.c.m. of blood to his wife, who had apparently contracted the infection from him. The patient, who was pregnant and desperately ill, showed marked and improvement. In the other case, receiving only 50 c.c.m. of convalescent blood, no apparent benefit was obtained.

Our patient seemed to show a remarkable, though transient, response to the first transfusion; this was manifested by a drop in temperature to normal, and by definite clinical improvement. The second transfusion appeared to have no effect. The third seemed to benefit him somewhat without affecting the temperature. The amounts of blood given on each occasion were small, as circulatory failure was feared in a larger transfusion. Yet the smallest transfusion, the first, appeared to have the greatest effect. The first donor was the most severely ill of the three and had been longer convalescent than the others. Thus it might be supposed that his serum would have a higher antibody titre than the others.

Summary and Conclusions

A case of fatal atypical pneumonia with encephalitis is presented, with necropsy findings. The incidence of encephalitis in atypical pneumonia is discussed.

Convalescent blood transfusion in atypical pneumonia is considered.

Special thanks are due to Lieut.-Col. Yale Kneeland, jun., M.C., U.S.A., for the unpublished data recorded above. We are deeply indebted to Lieut.-Col. John B. Hazard, M.C., U.S.A., for the histopathological descriptions and review of findings in the reported case.

THE FAILURE OF H 11 TO INHIBIT GROWTH OF TUMOURS IN MICE

BY

W. E. GYE, M.D., F.R.C.P., F.R.S.

R. J. LUDFORD, D.Sc., Ph.D.

AND

HILDA BARLOW, B.Sc.

(From the Laboratories of the Imperial Cancer Research Fund)

The preparation known as H 11, which is being used in the treatment of cancer, is an extract of urine. It is claimed that the extract contains "anti-growth substances" which have "an inhibitory effect upon cancerous growth." The method of preparation of H 11 and the standardization of the "growth-inhibitory power" of the product by its effect in checking the growth of oat seedlings are described by Thompson and his collaborators (1941). Thompson, Holt, and Forbes Jones (1943) claim that certain fractions of urine have been obtained which stimulate the growth of transplanted tumours. The urine is fractionated by precipitation with copper salts; the precipitate is extracted with dilute hydrochloric acid, which yields a tarry substance partially soluble in sodium hydroxide. The part soluble in alkali is said to accelerate growth, and therefore it would appear that by removal of the "growth-promoting fraction" the "growth-inhibiting properties" of the residue are increased. The improved extract is called 80 K.

It is not our purpose to examine or discuss the general questions of "growth promotion" and "growth inhibition" in relation to the problems of the pathology and treatment of cancer. We wish simply to put on record the results of experiments designed to test whether H 11 or the new improved preparation obtained after precipitation with copper salts does in fact inhibit or affect in any way the growth of cancer cells. Mr. J. H. Thompson of Hosa Research Laboratories has provided generous supplies of H 11 and of his new preparation 80 K; for his kindness we wish to express our indebtedness.

General Remarks on the Testing of "Cancer Cures"

In these laboratories we have gradually worked out routine methods of examining substances supposed to have valuable therapeutic properties for cancer. Our first step is usually a test of the direct action of the substance on cancer cells. For this purpose we use the technique of tissue culture. The substance to be tested is applied in various dilutions to cultures consisting of growths of normal and malignant tissues. The growth of the tissues is measured before and after varying periods of treatment. Control cultures are measured at the same time. From the two sets of measurements the extent to which normal and malignant growth are influenced by the substance can be calculated. Confirmatory tests are made by adding the substance under investigation, in the weakest concentration previously found to arrest malignant growth, to the

media used in preparing the cultures of normal and malignant tissues. Growth of normal tissues in such cultures, and concurrently no growth of the malignant tissues, would indicate a specific inhibitory action upon malignant growth. Treated cultures are examined microscopically for any cellular changes that might have been induced. The estimation of the significance of any changes requires a thorough acquaintance with the morphology of the tissues employed, during both growth and degeneration.

Our second step is to test the effect upon transplantable tumours growing in animals. A convenient method is to take one of the well-known transplantable tumours which have been observed over a period of years and whose growth behaviour is well known. It is important to select a tumour which when grafted gives a high percentage of "takes" and which recedes rarely. Many tumours which are widely used in cancer research are apt to retrogress after some preliminary growth. Such tumours are obviously unsuitable for research in therapeutics. An example of such a tumour is the Brown-Pearce skin carcinoma of the rabbit. The Imperial Cancer Research Fund possesses two transplantable mouse cancers which are eminently suitable for testing chemotherapeutic substances; they are the mammary carcinoma No. 63 and the spindle-cell sarcoma No. 37. Both graft easily, giving 95 to 98% of "takes" in mixed laboratory stock mice; both tumours grow steadily and kill the host in three to four weeks. Retrogressions are not more than about 1%. Injections of the therapeutic substance are made at a site remote from the tumour and are not begun until the graft has become vascularized and the "daughter tumour" is palpable.

Although these two well-known transplantable tumours are suitable for preliminary tests of the "growth-inhibitory" properties of any substance or preparation, we should not regard even a conspicuous retardation of tumour growth as being valid unless confirmation could be obtained on tumours of a homozygous strain of mice grown in the same strain. The grounds for such scepticism are well known and have often been stated in Reports of the Imperial Cancer Research Fund. Briefly the reasons for this extra precaution are as follows:

The tumours 37 and 63 occurred sporadically in two mice of mixed stock more than 30 years ago, and grafting was carried on, again in mixed stocks, until grafts grew readily in a high percentage. These tumours have now been carried through hundreds of generations of mice, but they are still foreign cells so far as the grafted host is concerned. There is in some mice an antagonism to these foreign cells, and in such mice retrogression of grafted tumours occurs. In spontaneous tumours of mice or men the cells of the tumour belong to the body, are a part of the body, and there is no such resistance to their presence in the body. The final test of any therapeutic method in cancer must evidently be made on spontaneous tumours, since these are the strict equivalent of human cancer; the variations which naturally exist among tumours must of course be kept in mind. Spontaneous tumours, even if of the same organ—for example, cancers of the breast—do not all grow at the same rate and behave in the same way. While the majority of mice with such tumours survive comparatively short time—a matter of weeks—after being noticed clinically, some live for months. There is thus no uniformity in the growth rate of the tumours, and consequently, in order to get reliable therapeutic results of an order short of rapid complete cure, it is necessary to treat large numbers of animals, leaving an equal number of untreated controls. It is probable that some of the good reports and the optimism which seem to accompany many "cancer cures" tried out on human beings have their source in the fact that some cancers do not kill their hosts quickly. The case which naturally survives a long time and which is under new treatment may be regarded as a proof that the new treatment has been to a certain extent effective. The credit belongs to Nature, not to Art. As a consequence of such apparent success other cases are treated similarly, and this goes on until at last the remedy is abandoned.

We are able to evade these complexities and to detect minor inhibitory effects by the use of homozygous strains of mice. Tumours arising in a homozygous strain grow uniformly when

grafted in mice of the same strain; there is no resistance to their growth, and such tumours are for practical purposes comparable with spontaneous tumours. The strains commonly used in the laboratories of the Imperial Cancer Research Fund are Strong A, Paris R 111, and C 57 black.

Results of Treatment with the Preparations H 11 and 80 on Animals bearing Tumours

The following tumours have been used in our tests:

- (1) Strong A carcinoma growing in pure-line Strong A mice; 10 treated and 6 controls.
- (2) Methylcholanthrene C 57 sarcoma growing in C 57 mice; 6 treated and 6 controls.
- (3) Mammary carcinoma 63; 6 treated and 6 controls.
- (4) Spindle-cell sarcoma 37; 6 treated and 6 controls.

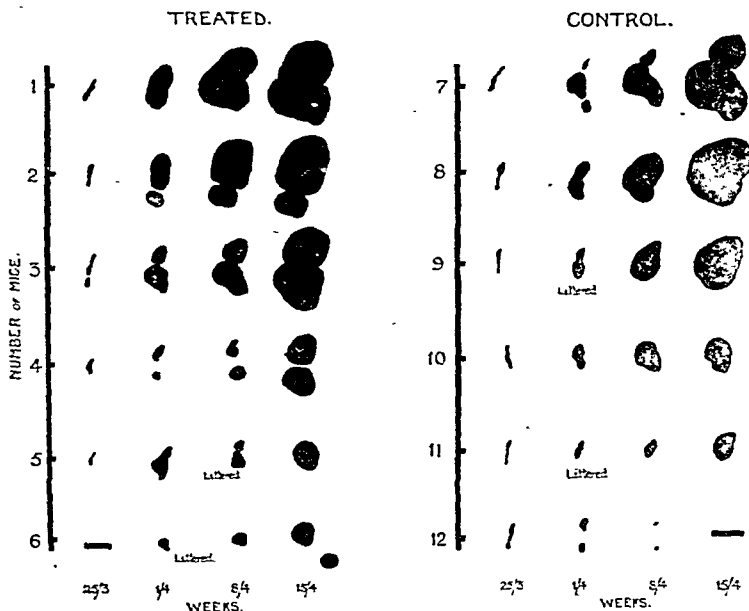

Mr. Thompson recommends the injection of 1 c.cm. intraperitoneally twice daily. Although we cannot believe intraperitoneal injections are of vital importance in the treatment—and it is unlikely that the recommendation is inspired upon in the treatment of human cases—we have nevertheless followed Mr. Thompson's method in three out of the tests, but always with due regard for the health of the animals. Intraperitoneal injection of 1 c.cm. twice a day becomes an ordeal for a 20-g. mouse; it is the equivalent of 14 lb. of fluid injected daily into the peritoneal cavity of a 10-st. man. As soon as the weight of a mouse began to appreciably the subcutaneous route was employed in order to give the animal a chance to recover. It should be noted that any treatment which depresses the animal's health, even an intercurrent infection, may retard the growth of a transplanted tumour. Many transplanted tumours cease to grow, or the growth rate falls strikingly, when the host is pregnant. This applies particularly to the mammary carcinoma No. 63. It will be observed from these brief comments that thorough and critical examination of a "cancer cure" demands experience and knowledge of the behaviour of transplantable tumours.

The rigid application of these rules has been relaxed in our tests of H 11. Thus with tumour 37 we "favoured" the remedy by infiltrating the growing margins of the tumour with H 11; while with tumour 63 almost all the rules were broken as will be shown later. With Strong A carcinoma and C 57 sarcoma we adhered strictly to the rules which we had adopted to exclude a deceptive appearance of a favourable effect.

In all our experiments with mice the tumours in the treated animals grew steadily and at the same rate as in the controls. We could distinguish no "growth-inhibitory" effects whatever. With the rapidly growing tumour 37 the growth of both treated and untreated tumours was so rapid that the experiment came to an end after 11 days: the tumours had become so large that further treatment was unjustifiable. The Strong A carcinoma grows more slowly, and treatment has been more prolonged—30 days; but again there was no evidence of a checking of growth or of any alteration in the cellular structure of tumours of animals killed during the course of treatment. The C 57 sarcoma was likewise unaffected.

One experiment only need be given in any detail, since it is representative in its negative results. Moreover, it was long after it had become evident that H 11 does not inhibit the growth of tumours, and was consequently planned to give the treatment every advantage that could be justifiably arranged. In the first place, we were enabled to use the latest improved extract 80 K, which, in Mr. Thompson's words, "has proved particularly potent as an inhibitor to malignant growth." In the second place, instead of grafting the tumour cells in ordinary mixed stock mice, in which the tumour grows very rapidly we grafted 12 mice of the inbred homozygous strain Paris R 111; the tumour cells grow more slowly in these mice, especially during the ten days following grafting, and regressions are more common. The tumour cells were thus placed in a comparatively uncomfortable environment, and it might be expected that a "growth inhibitor" would have a good chance to show its powers in such circumstances. The rule for testing chemotherapeutic substances were further violated by beginning injections of the extract only four days after grafts had been made—that is, a week before any daughter tumour could be palpated. The "growth inhibitor" was

jected twice daily—mostly intraperitoneally, but subcutaneously when the health of the animals became affected—from March 22 to April 5 inclusive; 25 mice in all. The accompanying chart illustrates the growth of the treated and untreated tumours. A glance at it shows that Mr. Thompson's extract has not inhibited the growth of the tumours; there is no difference beyond chance variation between the treated and untreated animals. In this experiment the lack of "growth-inhibitory" power became evident very early; for in spite of injections being started before palpable tumours had appeared and when the amount of living tumour tissue would not have been more than 0.2 c.cm. — the volume of the original inoculum-measurable tumours equal to those in the control mice were present after 8 days of treatment. These continued to grow normally, as the chart shows. The sizes attained by the tumours can be gauged by the weight of tumour in Mouse 1 in the chart on April 15; it was weighed after removal, and weighed 9.9 g.

Paris R 111 strain of inbred mice grafted with mouse carcinoma 63 on March 18, 1943. Mice 1 to 6, inclusive, treated with 80 K. Injections were begun on March 22, and were continued daily to April 15.

From the results of these investigations we conclude that H 11 has no "growth-inhibitory" effects on the tumours used in the experiments.

OBSERVATIONS ON THE USE OF H 11 IN CARCINOMA

BY

H. A. KIDD, F.R.C.S.Ed., M.R.C.O.G.

Medical Superintendent, Kingston County Hospital,
Kingston-on-Thames

During the past two years an increasing number of workers have described growth-inhibiting properties of urinary extracts. Turner (1939) indicated an inhibiting effect on an alcoholic fraction of urine, while Bowman and Mottshaw (1941) studied the growth-inhibiting properties of a similar extract on tumour growth. Other workers include Rohdenburg and Nagy (1937) and Murlin *et al.* (1939), who claimed anticarcinogenic properties for such extracts. Thompson *et al.* (1941) published a preliminary account of the preparation of an alcoholic fraction of urine named H 11, and described not only its biological properties and anticarcinogenic action in transplanted animal tumours but also the inhibitory effect on human cancer.

The Present Investigation

An investigation into the effect of H 11 extract on carcinoma as begun at the Kingston County Hospital in Oct., 1940, and is now thought advisable to issue an interim report, although no conclusions can be drawn, as the cases have not been followed up for a sufficient period.

Of the 51 advanced cases 14 received insufficient treatment, and of the remaining 37 patients 11 are dead and no reply was received from 5. Of the 21 patients known to be alive 4 have been under observation for under one year, 12 for over

one year, and 5 for over eighteen months. All the surviving cases except two received some other form of therapy, and in these two—Nos. 18 and 38—the diagnosis was not confirmed, as biopsy could not be performed.

The series (see Table) contains different types of carcinoma situated in various parts of the body. In most instances the condition was inoperable, and usually the patient was in poor general health, although there was considered to be a sufficiently reasonable expectation of life to justify treatment. This period of time was assessed at six weeks in accordance with the statement made by Thompson that objective signs of improvement do not usually occur until such an interval of treatment has elapsed. Some cases had other treatment, including operation and radium, but with few exceptions they were cases in which the operation or radium therapy was considered to be insufficient to eradicate the local disease.

There is some evidence that in a few cases the rate of growth has been slowed up or inhibited, but in no case confirmed by section has, as yet, any growth disappeared as the result of H 11 therapy only. Further research is essential in order to purify the extract, and a more satisfactory method of dosage must be evolved so as to keep the concentration in the blood at a constant level.

No case of carcinoma should be treated by H 11 alone unless a competent surgeon has advised that it is inoperable and unsuitable for radiotherapy, etc. Treatment must be given for at least six months, and the cost should be carefully considered before advising or starting this form of therapy.

H 11 extract has been supplied for this investigation by the generosity of Standard Laboratories, who have prepared the extract. All the research and experimental work has been carried out at the Hosa Research Laboratories by the Director of Research, Mr. J. H. Thompson, and his staff.

Case	Age and Sex	Date of First Inj.	Pathology	Previous Treatment	No. of H 11 Inj.	Result of Examination April, 1942	Result of Examination October, 1942
1	F 57	7/10/41	Infil. left broad lig.; col- lapsed carc. vagina	Radium	63	Less pain. Died 3/1/42	
2	F 35	19/2/42	Adenocarc. breast; sec. lungs and retina	—	496	Less pain; growths sta- tionary	Wt. 9 st. Pain bad in shoulders. Totally in- capable of getting about, but not getting weaker
3	F 39	4/3/41	Solid trabecular polygonal carc. cervix, Grade III	Radium	24, irreg.	Died Sept., 1941	
4	F 61	17/2/41	Carc. cervix, Grade III	Radium; hysterectomy; pre-sacral; neurectomy	950	G.C. v. good 1/5/42. N.A.D. per rectum, vagina, and pelvis; no pain, no dis- charge	G.C. good; rather pale; pain or discharge; vom- iting full day; wt. 9 st. stationary. P.R. utero- sacral thickened
5	F 46	21/5/41	Squamous carc. cervix, Grade III-IV	Pre-sacral neurectomy; radium	22, irreg.	Died 2/12/41	
6	F 53	7/6/41	Squamous carc. cervix, Grade III	Radium; pre-sacral neur- ectomy	20, irreg.	Died 16/8/41	
7	F 56	11/2/41	Solid trabecular polygo- nal and cubical carc. uterus	Radium; subtotal hyster- ectomy	120	Died 21/12/41	
8	M 69	11/7/41	Carc. prostate; renal calculi	Suprapubic cystotomy	30, irreg.	Died 6/9/41	
9	M 20	7/1/42	Mucus-secreting carc. rectum	Colostomy	62, irreg.	Died 10/3/42	
10	F 46	7/1/42	Mammary carc.; spastic paraplegia	—	31, once daily	Return of sensation in lower limbs. 19/3/42. Died 28/4/42	
11	F 56	6/10/40	Papillary carc.; cyst ovary; sec. in peritoneum	Total hysterectomy	119, irreg.	G.C. v. good; no pain, no ascites	Letter states now well. No symptoms
12	F 46	18/3/41	Carc. stomach and ovary	—	10	Died 27/3/41	
13	M 55	26/2/41	Carc. stomach	—	21	G.C. fair; no vomiting	Dead
14	F 60	21/8/40	Carc. uterus	Total hysterectomy; supra- pubic cystotomy	84, once daily	Died 10/2/41	
15	M 68	10/10/40	Carc. stomach and lower end oesophagus	Gastrostomy	22, irreg.	i.s.q.	No reply
16	M 70	18/12/41	Columnar carc. stomach	—	120, irreg.	Died 25/2/42	
17	F 51	July, 1941	Malignant ovarian; numer- ous small metastases; ascites	Laparotomy; left oophor- ectomy	520	N.A.D. abdomen or pelvis. G.C. v. good; gaining weight; no pain, no ascites	G.C. good; no pain or sym- ptoms. Injections March. No signs of re- currence. Gaining weight Very well; no symptoms or abnormal physical signs
18	F 60	Oct., 1940	Carc. rectum; sec. liver. Not confirmed by section	Laparotomy	460	N.A.D. per rectum except slt. thickening of recto- vaginal septum. G.C. very good	
19	M 72	Feb., 1941	Carc. rectum	Colostomy	650	Growth now involving anus. Wt. constant; G.C. i.s.q.	Gets about, but G.C. and pain+. Refuse further injections; grow- th extending.
20	F 56	Dec., 1941	Carc. cervix, Grade III	Radium; pre-sacral neur- ectomy	186	No ulcer, no pain, no haemorrhage; gain in wt.; G.C. imp.	G.C. good; wt. 12 st. 6 lb. no symptoms or signs of recurrence
21	F 68	Dec., 1941	Carc. vagina	Colostomy; pre-sacral neurectomy; rt. int. iliac ligatured	182	G.C. improved, less dis- charge; losing weight. Died 18/6/42	
22	F 60	May, 1941	Transitional carc. cervix, Grade III	Radium; pre-sacral neur- ectomy	380	G.C. good; gaining weight; no pain	G.C. v. good; wt. 11 st. 13 lb.; no pain or sym- ptoms, slight thickening of rt. utero-sacral lig.
23	M 63	July, 1941	Cylindroma of salivary glands	—	248	Mass of glands in neck enlarging	Dead
24	F 53	Jan., 1942	Solid trabecular transi- tional and squamous carc. cervix, Grade III	Radium; laparotomy; pre- sacral neurectomy	188	N.A.D. in abdomen. G.C. v. good; no discharge, no haemorrhage; gain- ing weight	No reply
25	F 45	June, 1941	Squamous and prickle- celled carc. uteri, Grade III	Radium; subtotal hyster- ectomy; colostomy	1,116	No pain; gain wt.; N.A.D. in pelvis; G.C. very good	G.C. v. good; wt. increas- ing; no symptoms or signs of recurrence. Col- ostomy to be closed.
26	M 66	Mar., 1941	Carc. bronchus	—	730	Pain relieved for a time. Mass in neck now ulcerat- ed through skin	Dead
27	F 53	May, 1941	Solid trabecular polygonal and transitional carc. cervix	Radium; Wertheim's hys- terectomy; pre-sacral neurectomy	744	No pain; no discharge; N.A.D. in abdomen. G.C. impd.; gain in wt. Vesico-vaginal fistula from radium necrosis	G.C. good; wt. increasing 9 st. 12 lb. No recurrence Has vesico-vaginal fistula; some thickening of rt. utero-sacral lig.
28	F 79	Apr., 1941	Transitional and squamous trabecular carc. cervix, Grade III	Radium	616	Less pain. Died Dec., 1941	
29	F 75	June, 1941	Malignant melanoma of neck	Local excision	342	No recurrence. Two months after discontinu- ing H 11 small gland appeared. Block dis- section April, 1942	G.C. fair; wt. 8 st. 8 lb. increasing. Some pain in shoulder, but x-ray N.A.D. and no signs of recurrence
	M 44	20/4/41	Carc. rectum; metastases in abdominal and in- guinal glands	Colostomy	153	Primary growth i.s.q.; in- guinal glands smaller. G.C. good; gain in weight. Died 25/4/42	
31	F 58	Sept., 1941	Solid trabecular and squa- mous carc. cervix, Grade III	Radium; pre-sacral neur- ectomy	424	No pain, no discharge; gain wt. G.C. v. good	No pain or discharge. Still having 5 c.cm. daily
32	F 39	Feb., 1942	Gastric carc.	Laparotomy	220	Little pain; G.C. fair; vomiting	Now complains of pain ar- rounding stomach and abnor- mal tumour, probably Krukenberg
33	M 68	27/6/41	Carc. prostate	—	538	25/4/42: Prostate i.s.q.; has retention of urine; G.C. satisfactory	No reply
34	M 70	Dec., 1941	Columnar carc. prostate; mass in left lung	Deep x-ray	58	Died Feb., 1942	
35	F 62	Jan., 1942	Carc. cervix	Radium; pre-sacral neur- ectomy	98	Died 9/3/42	
36	F 56	Sept., 1941	Squamous pricked and horny carc. cervix, Grade III	Radium	256	Repeat radium March, 1942. Growth checked; G.C. impd.; gain in wt.; no discharge, pain, or incontinence. Died 28/4/42	
37	F 66	July, 1941	Squamous carc. cervix, Grade II-IV	Radium; diathermy	1,116	No pain; G.C. satis- fying. N.A.D. in abdomen; utero-sacral lig. still thickened	G.C. v. good; wt. 14 st. 4 lb. increasing; no symptoms no signs of recurrence but some thickening both utero-sacral lig. injections now stopped

Case	Age and Sex	Date of First Injec.	Pathology	Previous Treatment	No. of H 11 Injec.	Result of Examination April, 1942	Result of Examination October, 1942
38	M 53	June, 1941	Carc. prostate; not confirmed by section	—	620	Gland normal; gain in wt.; G.C. v. good; micturition normal	G.C. v. good; no symptoms; no nocturnal frequency. P.R., prostate soft; rt. lobe \pm
39	F 58	Oct., 1941	Squamous carc. cervix, Grade III	Radium	744	No discharge, no symptoms, no pain; G.C. impd. 22/4/42	G.C. v. good; wt. increasing, 7 st. 13 lb.; no pain or symptoms; no signs of recurrence. Injections now stopped
40	F 47	July, 1941	Squamous carc. of cervical stump; had hysterectomy several years previously for fibroids. Large ulcerating mass	Radium; pre-sacral neurectomy	558	V. sat. condition; some scarring vaginal walls; no pain; a little loss of wt.	G.C. v. good; lost 10 lb. in wt. since April; has thickening rt. utero-sacral lig. and small mass in pelvis. To have further injections
41	F 45	Aug., 1941	Squamous carc. cervix, Grade III	Radium; pre-sacral neurectomy; Wertheim's hysterectomy	558	N.A.D. abdomen; no pain; G.C. v. good; scarring and a little thickening of vaginal vault	G.C. v. good; wt. 11 st. 6 lb. Injections stopped in April, 1942. No symptoms; P.R., both utero-sacral thickened
42	F 47	Sept., 1941	Carcinoma cervix, Grade IV	Radium	447	N.A.D. abdomen; no haemorrhage; no discharge; G.C. v. good. P.V., scarred cervix	Gradually lost wt. and pain recurred. Died 11/8/42
43	F 56	Oct., 1941	Solid trabecular transitional and squamous carc. cervix	Radium; pre-sacral neurectomy	249	G.C. v. sat.; gain in wt., 10 st. 7 lb.; no pain; slight cervical scarring	G.C. good; wt. 11 st. 2 lb.; no symptoms but tiredness; utero-sacral ligaments thickened. To have further injections
44	M 60	Sept., 1941	Carc. prostate	—	98, irreg.	—	Doctor states G.C. good; wt. stationary; no pain; working, and feels well
45	M 21	Jan., 1942	Carc. rectum	—	188	Died	
46	F 46	Jan., 1942	Carc. cervix	Radium	150	Condition worse	Died
47	F 26	30/10/41	Carc. stomach	Gastrectomy	240	27/2/42: Epigastric tumour; G.C. deteriorating; losing wt.; vomiting	No reply
48	F 60	13/1/41	Carc. uterus	Wertheim's and radium, followed by recurrence and suprapubic cystotomy	200	No improvement. Died 10/2/42	
49	F 70	9/10/41	Carc. cervix, Grade II	Radium	300	22/4/42: Satis; G.C. good; no sec. palpable V. rapid growth, causing intestinal obst. Died 19.12.40 ? accelerated by withdrawal of growth-inhibiting factor	Dead
50	F 29	1/11/40	Carc. ovary	Ovariectomy; glands+	19, stopped at patient's request	19/6/42: Operable. Growth slowly increasing; started approx. 1" in diameter, now 1 1/2"	No reply
51	F 60	28/8/41	Carc. breast (scirrhus)	Nil; patient refused operation or radiotherapy	540, irreg.		

I wish to express my thanks to the medical and nursing staff of the Kingston County Hospital for their assistance, and to the general practitioners who have co-operated in giving the injections to the patients in their own homes. In particular I am indebted to Mr. J. V. O'Sullivan for his great interest in this research and for his valuable suggestions.

CUTANEOUS HYPERSENSITIVITY TO SULPHONAMIDES

A REPORT OF 12 CASES

BY

R. G. PARK, M.B., M.R.C.P.

Major, N.Z. Medical Corps

The following cases illustrate a type of sulphonamide eruption which is being recognized with increasing frequency in the Middle East, but to which I am unable to find any reference in the literature at my disposal. In a previous report from this hospital on sulphonamide eruptions of the photosensitive type (Park and Platts, 1942) it was pointed out that these rashes almost invariably begin after 7 to 10 days of sulphonamide therapy, when there is presumably a high concentration of the drug in the blood. One case, however, was quoted in which there was a severe dermatitis beginning immediately after the first doses of sulphanilamide, differing from the delayed eruptions in its exudative character. An analogy was drawn between this condition and the experimental observations of Epstein (1939), who obtained erythematous and exudative reactions respectively to ultra-violet irradiation of the sites

of two successive injections of sulphanilamide, nine days apart. This phenomenon he christened "photo-allergy." The cases reported below are all of the immediate type, some of the generalized ones being unmistakably photosensitive, and it has been found that all of them have had sulphonamides applied to the skin some time before their eruptions.

Case I

On Aug. 16, 1942, Private B., aged 36, developed a seborrhoeic intertrigo of the left axilla. On the 19th this became pustular, and sulphanilamide ointment was applied, clearing up the secondary infection and leaving the intertrigo as before. He gave a history of a widespread eruption, lasting several weeks, following sulphanilamide dressings to a wound of the back 8 months previously. On Aug. 23 he developed acute tonsillitis, and was given three 0.5-g. doses of sulphanilamide by mouth. That evening the intertrigo became worse and a general rash appeared.

Next day, on admission to hospital, he showed a weeping eczematous intertrigo of the axilla and a diffuse papular dermatitis of the trunk and limbs. He received no more sulphanilamide until Sept. 1, when his tonsillitis recurred. Three 4-hourly doses of 1 g. were then given, and that evening the entire eruption recurred, more severely than the first time. It took two weeks to clear. On Sept. 23 0.5 g. of sulphapyridine caused a mild erythematous reaction at all the previous areas, lasting two days. On Sept. 26 1 g. of sulphaguanidine produced no reaction. On the 27th 5 g. of sulphaguanidine gave a mild erythematous reaction. On Oct. 1 1.5 g. of sulphathiazole caused no reaction.

On Oct. 4 a paste consisting of equal parts of sulphanilamide, starch, soft paraffin, and lanolin was applied to several test areas. This caused an immediate reaction in the left axilla, but none on any other part of the skin. Intradermal tests were carried out with 0.01, 0.1, and 1% of sulphanilamide in normal saline, using controls of normal saline alone. Only the 1% gave a reaction, consisting of a raised erythema, beginning in about 4 hours and lasting 24 hours.

Case II

On Aug. 1, 1942, Leading Aircraftman T., aged 38, suffered abrasions of the left elbow which became infected and were treated with eusol and sulphanilamide, applied locally. On Aug. 8 ar

eruption appeared; by Aug. 28, when he was admitted to hospital, this had spread to involve the whole forearm. It was an acute weeping dermatitis. On Sept. 9 he developed acute tonsillitis, and was given sulphanilamide in an initial dose of 2 g. and three 4-hourly doses of 1 g. That evening he developed an acute papulo-vesicular dermatitis of the trunk and limbs and an exacerbation of the left forearm.

Test applications of sulphanilamide paste were negative. Sulphapyridine 2 g. gave no reaction, but there was an erythematous reaction of the trunk after 5 g. of sulphaguanidine. No reaction was obtained from 1.5 g. of sulphathiazole. Intradermal and scratch tests with 1% sulphanilamide were negative.

Case III

About the middle of July, 1942, Private M., aged 23, developed a "desert sore" (ecthyma) of the right forearm. It was treated at first with eusol and later with local application of sulphanilamide and cod-liver oil: a dermatitis followed in the area treated. By the end of August the whole forearm was affected, and then the face, hands, and feet. He was admitted to hospital, and on mild applications the condition settled down in two to three weeks.

On Sept. 18 one application of sulphanilamide paste was made to the right forearm, where an immediate acute exudative reaction took place. On Sept. 25 a test dose of 0.5 g. of sulphanilamide was given orally. A few hours later the patient developed an acute vesicular dermatitis of the right forearm and both hands and feet. On Sept. 27 a sulphanilamide paste was applied to the face, with an immediate reaction, and to the left forearm (which had never been the site of eruption), with no reaction. On Oct. 13 0.5 g. of sulphapyridine gave no reaction, but 2 g. next day produced a mild erythema at all the previous sites, lasting a few hours only. From Oct. 16 to 22 doses totalling 12 g. of sulphaguanidine and 4.5 g. of sulphathiazole were given with no effect.

Case IV

On Aug. 6, 1942, Sapper R., aged 35, suffered an abrasion of the left elbow, which developed infection and was dressed with sulphanilamide. A dermatitis subsequently appeared on the forearm, and by Aug. 18 had spread to other parts of the body.

He was admitted to hospital on the 20th with a bullous dermatitis and subcutaneous oedema of the left elbow, a papulo-vesicular eruption of the face, scalp, neck, trunk, arms, hands, and legs, and a mild crural and intergluteal intertrigo. His temperature was 101°. He was given 2 g. of sulphanilamide followed by 1 g. 4-hourly; the drug was discontinued two days later, since there was no improvement, the temperature chart varying from 99° to 102°. This then subsided in two more days and his skin steadily improved. On Sept. 26 1 g. of sulphanilamide was given with no reaction, but on the next day three similar doses caused a sharp flare-up of the left arm and a milder erythema of the face, neck, hands, and feet.

On Oct. 6 three doses of 5 g. of sulphaguanidine gave a papulo-vesicular reaction on the left forearm only. Sulphapyridine 15 g., in divided doses over three days, gave a mild papular reaction on both forearms. Applications of sulphanilamide paste, and intradermal and scratch tests, were negative with 1% sulphanilamide.

Case V

About the beginning of Sept., 1940, Warrant Officer D., aged 40, had lesions of impetigo and ecthyma on the arms, which were treated with acriflavine and later with sulphanilamide powder. In the middle of September areas of dermatitis appeared on both arms and on the 29th an eruption occurred on the hands, legs, face,

and he was admitted to hospital on Oct. 3, when he had circumscribed areas of moist dermatitis round the sites of previous ulcers on the left forearm and right hand. There was a more recent vesicular and pustular dermatitis on the legs, hands, and face, and in scattered areas on the trunk. Intradermal tests with sulphanilamide gave a reaction with the 1% strength only, starting in 24 hours and lasting 4 days. On Oct. 13 0.5 g. of sulphanilamide, given orally, caused irritation on the existing areas and the appearance of a few new papules. Application of sulphanilamide paste to the area of subsiding dermatitis on the left forearm produced a distinct erythematous and papular reaction.

Case VI

About the middle of Aug., 1942, Private R., aged 25, developed some desert sores on both knees. These were treated by dusting sulphanilamide powder on them and dressing them with acriflavine gauze. An ulcer on the right knee healed in three days, but two on the left knee healed only very slowly. About the middle of September a patch of dermatitis began round each of these, with which he was admitted to hospital on the 21st. They were about 2 to 5 in. in diameter, with a weeping and scaly surface and fairly sharp margins. Both these areas became dry on rest in bed and simple dressings. On Sept. 29 one application of sulphanilamide

paste to the milder of these areas caused it to weep profusely, while the other remained dry. Applications to the other knee gave no reaction.

A positive reaction was obtained to 1% intradermal sulphanilamide, none to the other strengths. This was a raised erythematous area, 1/2 in. in diameter, beginning in 18 hours, reaching a maximum in two days, desquamating on the surface, and finally fading in about 10 days. Scratch tests with the same dilutions were all negative. On Oct. 13 0.5 g. of sulphanilamide was given, with an immediate exudative reaction on both areas, together with a papular dermatitis on the face, arms, trunk, and other leg. The patient recalled that a similar eruption had appeared for a few days when he was having his leg dressed with sulphanilamide. On Oct. 19 and 24, respectively, weeping reactions were obtained in both areas, but not on other parts, from oral doses of 0.5 g. of sulphapyridine and 1 g. of sulphaguanidine. On Oct. 31 0.5 g. of sulphathiazole was followed by irritation but no exudation, and on Nov. 4 a total of 5 g. in divided doses caused a definite recurrence of exudation.

Case VII

The case of Leading Aircraftman C., aged 25, was one of pre-existing eczema which developed an intercurrent hypersensitivity to sulphonamides. Between the ages of 5 and 7 he had suffered from intermittent eczema of the face and hands. There was a family history of asthma and a personal history of nervousness and dyspepsia. On the way to the Middle East in Aug., 1941, a septic abrasion of the right index finger started a scaly and vesicular eczema of the hand, which steadily spread and had recently begun to involve the left hand. He had sulphanilamide ointments applied at intervals for four months before his admission to hospital on Aug. 29, 1942. He settled down with mild application and fractional doses of irradiation.

On Oct. 6 0.5 g. of sulphanilamide was given. An exacerbation took place on both hands, and in addition a papular dermatitis appeared on the right forearm. Intradermal and scratch tests and the application of sulphanilamide paste were all negative. Successively larger doses of sulphapyridine and sulphaguanidine were then given from Oct. 17 to 29. Papular reactions were obtained on the right forearm with 3 g. of sulphapyridine and 40 g. of sulphaguanidine in divided doses.

Case VIII

Sapper H., aged 42, began in July, 1942, to suffer from boils in both axillae. Sulphanilamide powder was applied, between other treatments, at intervals over the next three months. At the beginning of October an eruption appeared in both axillae and became progressively worse. A week later he began to itch all over, and a milder eruption spread to the trunk and hands.

On admission to hospital on Oct. 16 he showed an acute exudative dermatitis and furunculosis of both axillae, and a papular dermatitis on the hands and scattered over the trunk. The dermatitis rapidly subsided and the boils improved steadily. One application of sulphanilamide paste to the left axilla caused a recurrence of dermatitis in both axillae, and a papular eruption when applied to an area on the right arm, which had not erupted before. By Nov. 4 both axillae were clear, and 0.5 g. of sulphanilamide was given by mouth. Next day he was covered with an irritable papular dermatitis of a photosensitive nature, being confluent on the face, neck, and trunk above the waist, moderate on the knees, mild on the lower trunk and legs, and absent from the inner surfaces of the upper arms. Both axillae were again the sites of a weeping dermatitis.

An intradermal test with 1% sulphanilamide was negative.

Case IX

About the beginning of Aug., 1942, Lieutenant P., aged 30, was wounded in the right hand and left knee. These were dressed, and he remained with his unit. Sulphanilamide powder was used. The wounds failed to heal, and about the beginning of September his knee underwent secondary infection, with inguinal adenitis and fever. On Sept. 5 he was sent to hospital, where he was treated at first with sulphanilamide locally, and afterwards, as there was no improvement, with other applications. He was almost healed on his discharge 6 weeks later. He was transferred to a convalescent home, where sulphanilamide powder was again applied, and in a few hours both areas were weeping profusely.

I saw him for the first time on the following day, Oct. 24, when he had areas of exudative dermatitis about 3 in. in diameter on the right hand and left knee. There was no adenitis or secondary infection. Dressings of Lassar's paste were applied and he was instructed to avoid sulphonamides locally and by mouth. By Nov. 2 the lesions had cleared, and he was given 0.5 g. of sulphanilamide by mouth. A few hours later a general eruption appeared. When next seen on Nov. 4 he showed an acute papulo-vesicular dermatitis, intensely irritable, and universally distributed from head to feet.

Case X

In June, 1942, Captain B., aged 30, was wounded in the right arm. The wound, suppurated and caused some surrounding pustular dermatitis, which persisted until August, when he was admitted to hospital. He had been treated with sulphanilamide powder locally at intervals during this time. About Oct. 8 he developed a small eczematous sore on the lobe of the right ear. Two days later similar sores appeared on the left leg, and after a further 24 hours these had progressed to a cellulitis, for which he was evacuated from the field. At the field ambulance he was noted to have bullae on the left shin, with surrounding cellulitis and a temperature of 100° . Sulphanilamide was started on Oct. 11: 2 g. followed by 1 g. 4-hourly. On Oct. 12 the bullae were larger and the oedema more extensive, with inguinal adenitis and oedema of the right ear, and a temperature of 101.3° . On the same day an eruption began on his hands and feet.

On reaching hospital on the 13th he showed cellulitis of both ears and legs, bullae on the left leg, and a vesicular and pustular dermatitis of the hands, face, and the area of his original wound of the right forearm. Sulphanilamide was stopped on Oct. 13. By Oct. 21 his skin was clear except for an infected ulcer on the left leg where the bullae had been. This slowly healed. He gave no reaction to the local application of sulphanilamide to any areas. Sulphathiazole 16 g. and sulphaguanidine 16 g. in divided doses gave no reactions. On Nov. 5 0.5 g. of sulphanilamide was given, to be followed by an irritable erythematous dermatitis of both legs below the knees and the skin on the right forearm at the site of his original wound.

This condition was considered to be a streptococcal infection, plus reaction to oral sulphanilamide, to which he had been sensitized by local applications two months previously.

Case XI

Corporal C., aged 26, had suffered from a mild eczema of the feet, hands, and trunk for two years, which had been almost quiescent over the past two months. On Oct. 13, 1942, a spot resembling impetigo appeared on the scrotum. It was treated with iodine. On Oct. 15 sulphanilamide and fomentations were applied three times. On Oct. 16 he was given 2-g., 1-g., and 1-g. doses of sulphanilamide by mouth. On the 17th a generalized irritable rash appeared.

He reached hospital on the 20th, showing a small area of weeping dermatitis on the right side of the scrotum, and a widespread papular dermatitis of the trunk and limbs. An intradermal test with 1% sulphanilamide caused an irritable area of raised erythema, 4 to 5 in. in diameter, lasting three days. Sulphanilamide paste applied on Oct. 31 caused no reactions. On Nov. 1 he took 0.5 g. of sulphanilamide orally. An immediate generalized eruption appeared, of a photosensitive type. It consisted of irritable papules, becoming confluent on the upper trunk, with a sharp lower margin at the waistline. It was also present on the face, arms, and legs, especially the exposed parts of the knees, but was absent from the axillae and the trunk below the waist.

Case XII

Lance-corporal H., aged 32, was operated on for hammer-toe on Sept. 17, 1942. His wound healed slowly, and sulphanilamide powder was applied intermittently to it over the next month. A mild degree of sepsis supervened, and at 10 a.m. on Oct. 21 he was given an initial dose of 2 g. of sulphanilamide, followed by 1 g. 4-hourly until 2 p.m. the next day—a total dose of 8 g. Two hours after the first dose he developed macules on his hands and feet. About 6 o'clock that evening he had a rigor and his temperature rose to 102° . Macules were then seen on his face and neck. His temperature continued between 102° and 104° , with a pulse rate of 100 to 120.

Seen on Oct. 24, he showed a morbilliform erythema, universally distributed, but confluent on certain of the exposed parts—face, neck, eyelids, and dorsum of the hands. It was scanty on the lower trunk and in the axillae—parts seldom exposed to the light. It was not irritable. Malaise was the only symptom, and there were no signs of measles or other exanthemata. The temperature fell by 10 a.m. on Oct. 25, and the rash had faded two days after that, except for a mild exfoliation on the face, neck, hands, and feet. There was a little secondary pustulation on the hands.

Discussion

All these cases show a cutaneous hypersensitivity to sulphonamides, apparently induced by their local application. When its sensitization has taken place dermatitis can be caused by the local application of sulphanilamide, and by the internal administration not only of sulphanilamide itself but of other drugs of the sulphonamide series. The reaction is proportional to the dose of the drug and to the degree of sensitivity (which varies considerably). In the same patient a large dose will cause a severe eruption, a moderate dose a mild one, and a small dose no eruption at all.

Three of the above cases were ones in which hypersensitivity could be expected, two being pre-existing eczemas and the

other a seborrhoeic subject with an axillary intertrigo. All the remaining cases were pyogenic skin infections of one kind or another. No cases were seen as a result of dressing clean wounds or burns with sulphanilamide. After a varying period of treatment patches of dermatitis appeared in the areas treated and steadily spread. In some of the cases there has finally been a rapid extension of the sensitivity to other parts, causing a widespread acute dermatitis.

The reaction to oral administration is the most sensitive. All of the above cases have flared up on giving sulphanilamide by mouth, usually with as little as one 0.5-g. tablet. Four out of six cases tested gave a reaction to sulphapyridine, but in rather larger doses. Four out of six reacted to sulphaguanidine in still larger doses. One case reacted only to sulphathiazole, but owing to shortage of this drug at the time it was not possible to test all patients with full doses. The reaction usually begins about 8 hours after administration. In 3 cases it has shown a typical photosensitive distribution, and in one case it has been accompanied by drug fever.

Sensitivity to local application is less marked. Of the 12 cases 6 reacted to it in the eczematous area where the original sensitizing applications were made. Other parts of the skin are much less sensitive. Even those areas which became inflamed on oral administration of the drug reacted to its contact in only one case. Patch tests on unaffected areas of skin, therefore, would not be of any diagnostic value in this condition.

Intradermal tests were positive to a 1% solution in 4 out of 10 cases tested. In a series of 10 control subjects they were negative in all cases. A positive reaction appears in anything from 4 to 24 hours, and lasts from 24 hours to a week. It consists of a raised area of dull erythema, and may itch considerably. Scratch tests gave no positive reactions.

It is not known how long this sensitivity persists. None of these cases has been under observation long enough for it to pass off, and no diminution has been observed in the degree of sensitivity with the passage of time. The cases have reacted for periods of up to two or three months after local sulphonamide therapy has been stopped.

In Case III, one of the most sensitive, an attempt was made to transfer the hypersensitivity by the Prausnitz-Küstner technique. Serum from the patient was injected intradermally into the arm of a normal subject (my own). A scratch test was performed 48 hours later on this site, with no reaction. Nor was there any reaction to the ingestion of sulphanilamide tablets by the subject.

Although hypersensitivity to many substances used locally on the skin may occur, its existence with sulphonamides is a more serious matter. It is easily seen that should these men get pneumonia, cerebrospinal meningitis, bacillary dysentery, or any of a large number of other diseases, their treatment with sulphonamides would be gravely hampered, if not rendered impossible. These cases present a strong argument against the indiscriminate use of sulphonamides as applications for skin infection or dressings for wounds. Other materials will usually do the job equally well, if perhaps not quite as quickly. It should be added that this does not apply to the introduction of sulphonamides into the depths of wounds, since in all cutaneous sensitizations it is necessary to have actual contact with the skin itself.

Most of the above cases have had sulphonamides applied for prolonged periods, and in Case VI an area of skin treated for only a few days escaped sensitization, in contrast to those treated for several weeks. This indicates that when these drugs are used it should be for as short a time as possible. Such a principle should not prove any hindrance in practice, since an infection susceptible to sulphonamides will be eradicated in a few days if it is going to be eradicated at all.

Summary

Twelve cases are described in which local sulphonamide therapy has caused sensitization dermatitis.

This is a serious drawback in the treatment of subsequent infections for which sulphonamides are really needed—e.g., pneumonia.

The fact that these 12 cases were seen in this hospital over a period of less than three months suggests that the condition

is by no means a rare one. It is to be suspected whenever eczematization occurs in skin lesions receiving local treatment with sulphonamides.

Intradermal and patch tests are of little value in diagnosis, which is best confirmed by the reaction which follows a small dose of sulphanilamide by mouth.

My thanks are due to Major B. C. Tate, R.A.M.C., who first drew my attention to the existence of this condition, and to the Director of Medical Services, N.Z.E.F., for permission to publish this paper.

THE MODERN TREATMENT OF GONORRHOEA

BY

Brigadier T. E. OSMOND, M.B.
Consulting Venereologist to the Army

The following article has been written in response to a request from the Editor, who recently received a letter from a surgeon saying he was "appalled by the way patients are being mistreated in general practice." I have therefore set out the treatment somewhat dogmatically, because my remarks are meant not for the venereologist but for the general practitioner, who may be none too familiar with either gonorrhoea or its treatment.

GONORRHOEA IN THE MALE

The incubation period is of some importance; a gonorrhoeal discharge usually starts 3 to 5 days after infection, with extremes of 2 to 10 days; do not believe the patient who says he has not indulged in sexual intercourse for several weeks or even months—he is either a liar or suffering from a relapse. It is said that non-gonococcal urethritis—and this is a very definite entity—has a rather longer incubation period: often a week or 10 days or more. Don't forget the possibility of an intra-urethral syphilitic chancre causing a discharge, in which case the incubation period is likely to be not less than 3 weeks.

Diagnosis

In a typical case there is a profuse greenish-yellow purulent discharge from the urethral canal; make sure that it does come from within the urethra and not, as in balanitis, from behind a tight foreskin. A thin watery discharge usually indicates chronic gonorrhoea or non-specific urethritis.

1. Take a loopful of the pus from within the meatus with a platinum loop and spread it thinly and evenly on a slide—or prefer two slides—and allow to dry in the air. Do not rub the slide the tip of the glass penis. Stain by Jensen's modification of 's method—gonococci appear as Gram-negative intracellular cocci. If there is likely to be any question of legal proceedings a wise plan to have the discharge cultured as well, in which case it is better to refer the patient to a pathologist before starting treatment.

2. Take a specimen of urine into two or more glasses; if the infection is recent, that in the first glass will be hazy owing to pus, and that in the second clear (anterior urethritis). If both glasses are hazy there is posterior urethritis as well. Add half an ounce or so of acetic acid to the urine in each glass; if the haze is due to pus it will not disappear; if due to phosphates it will clear.

If gonococci are found treatment may be begun; if they are not found take further specimens (smear and culture) next day, having told the patient to hold his urine all night or at least 4 hours before coming to see you. If gonococci are still not found refer the case to a specialist. You may get into deep water if you undertake chemotherapy without having made a definite diagnosis.

Only in urgent cases in which the diagnosis is clinically probable may chemotherapy be started pending the result of microscopical examination.

Treatment

The general practitioner should be chary of undertaking the treatment of gonorrhoea unless he has had considerable experi-

ence not only of the disease but of chemotherapy: gonorrhoea cases have a way of "going wrong," and the sulphonamide drugs are dangerous in unskilled hands. Many practitioners do not care to treat these cases, and there are plenty of venereologists and V.D. clinics available in most parts of the country. Remember, the average venereal patient is not a satisfactory one: if you cure him he shows little gratitude if you fail he is apt to turn nasty.

However, if you do decide to undertake treatment start the following lines. Don't forget the importance of general as distinct from specific treatment. During the acute stage patient should lead a quiet, peaceful, sedentary life, keep bowels well open with cascara or liquid paraffin, and avoid sexual intercourse, alcoholic and other stimulants, and pornographic literature. No special diet is necessary. Above all things he should avoid introspection; many of these patients take far too much interest in their disease and its treatment. This applies more particularly to those cases which do not react well to specific drugs. All patients should be warned of the contagiousness of their condition and of the necessity of simple hygienic measures to avoid infecting their own eyes and communal articles such as towels, baths, etc. While it is true that adults do not get gonorrhoea from such things as lavatory seats, nevertheless young female children are particularly susceptible to infection, and simple hygiene is desirable on aesthetic grounds alone.

Chemotherapy

Before starting this exclude previous intolerance and other contraindications such as certain dermatoses, blood dyscrasias, renal disease, jaundice, and neuritis, and ask the patient if he has already taken any sulphonamide. Remember that sulphonamides may cause vertigo: do not allow a patient to drive a car or pilot an aircraft while taking these drugs. Use optimum conditions from 80 to 90% of early acute cases can be cured by the best of the sulphonamide preparations without any other treatment. Those recommended are sulphadiazine, sulphathiazole (thiazamide, M & B 760), sulphapyridine (M & B 693), and sulphanilamide, in that order of merit; the first named is often unobtainable, and sulphathiazole is therefore the usual choice. Prescribe 5 g. (10 tablets) a day for 2 days; 3 tablets on rising, 2 at midday, 2 at tea-time, and 3 at bedtime; the tablets should be given crushed; two tumblerfuls of water or other bland fluid to be taken on each occasion. It is of utmost importance that the fluid intake should be at least 6 to 7 pints in the 24 hours in order to avoid the risk of haematuria which may be a very serious complication of treatment. If the patient shows a dramatic improvement at the end of 48 hours no further chemotherapy may be needed; if, however, there is still some discharge, or the urine is still hazy with pus, continue chemotherapy on the same dosage for a further 4 days; total—20 g. of sulphathiazole in 4 days. Then stop the drug. Insist on seeing the patient daily, preferably early in the morning, and do not give a prescription for, or supply, sufficient of the drug for more than one day: sulphonamide preparations cannot be obtained by the patient from a chemist without a prescription. The sulphonamide preparations appear to act best and to be less apt to cause haematuria or anuria when the urine is rendered alkaline; therefore prescribe 11 following from the start of the treatment:

Pot. cit. (or sod. cit.)	gr. xxx
Pot. bicarb. (or sod. bicarb.)	gr. xx
Chloroform water	ad 3ss

Sig.—One tablespoonful to be taken 4 times a day.

If the discharge clears in 2 to 4 days watch the patient daily for 7 days after the termination of chemotherapy, noting whether there is any discharge or heavy threads in the urine. If both are absent at the end of this period a presumptive cure has been obtained. If after 4 days' chemotherapy minor signs of urethritis persist, put the patient on to antero-posterior irrigations (into the bladder) of 1 in 10,000 potassium permanganate or 1 in 8,000 oxycyanide of mercury. (Before using the latter drug make sure the patient is not taking iodides in any form.) Irrigations should not be carried out by the patient himself but by someone skilled in the procedure. The lotion should be at blood heat, given with an irrigator, raised not more than 2½ feet above the patient's penis, and a nozzle of the fan type; the anterior urethra should first be cleansed, and the

solution then coaxed, not forced, into the bladder. Fill and empty the bladder two or three times, using 2 pints of the antiseptic lotion. Do not in any circumstances use a syringe or urethral treatment: syringing is an inefficient method, and serious consequences may result. If 7 days' irrigation fails to complete the cure you may give a second course of sulphonamide drug, but first have a total and differential white blood count done to avoid the risk of agranulocytosis: preferably use

different preparation—e.g., sulphadiazine, 6 g. a day for 4 days, or sulphapyridine, 5 g. a day for 4 days. If this second course of chemotherapy fails you may assume that the patient is sulphonamide-resistant, and further chemotherapy is not only useless but even dangerous.

Cases which resist chemotherapy and irrigation are most likely to be troublesome—look out for complications, especially epididymitis and prostatitis. The most efficient treatment for sulphonamide-resistant cases is artificially induced hyperpyrexia; this is a dangerous procedure unless carried out by an expert. The most effective method of raising the patient's temperature is the heat cabinet—e.g., the Kettering hypertherm or the induction therm—but as these cabinets are rarely available, recourse is usually had to simpler methods, such as intravenous or intramuscular injections of various forms of protein—e.g., typhoid or *coli* vaccine, sterile milk, peptone, or one of the various proprietary preparations.

If the patient is not cured after two courses of chemotherapy and irrigation refer him to a specialist; the same applies to those cases which show intolerance of the sulphonamides.

Intolerance to Sulphonamides

The following are the commoner side-effects of sulphonamides, with recommendations concerning them.

Side-effect	Recommendation
Headache, lassitude, disorientation, diplopia, insomnia	Unless severe, maintain dosage. Keep patient in bed
Pyrexia (above 100° F.)	Reduce dosage; force fluids; stop drug if temperature persists
Nausea, vomiting, epigastric discomfort, diarrhoea	If mild, maintain dosage but give a diet of staps and alkaline gastric sedatives. If more severe, reduce dosage or stop altogether
Conjunctivitis (sulphathiazole)	Imperative to stop drug and force fluids
Cyanosis	Exclude sulphur-containing foods and drugs. Do not stop drug unless severe. Give methylene blue 0.5 to 1 g. a day by mouth
Haematuria	Discontinue drug; force fluids. If oliguria or anuria develops call in a G.U. surgeon; urethral catheterization or nephrostomy may be indicated
Dermatitis	Avoidance of exposure to the sun assists in prevention. Discontinue drug. Induce diuresis; check leucocyte count
Agranulocytosis	May be ushered in by sore throat, headache, and fever; do blood count. Pentnucleotide 0.35 g. intramuscularly twice daily. Transfuse with fresh defibrinated blood
Haemolytic anaemia	Omit drug, induce diuresis, transfuse
Jaundice, toxic hepatitis, acute yellow atrophy	Imperative to discontinue drug

Summary.—In dermatitis (rash) and fever it is wise to stop the drug and force fluids. In conjunctivitis, acute haemolytic anaemia, haematuria, severe leucopenia, hepatitis, and jaundice it is imperative to do so. Remember that persons who have shown themselves susceptible in the past will almost certainly do so again. Therefore always question the patient as to previous idiosyncrasy before prescribing sulphonamide drugs.

Complications

These usually call for specialized treatment unless they react to the sulphonamides, and therefore will only be mentioned briefly.

Infection of Tyson's glands, situated on each side of the fraenum, and of the *para-urethral ducts*, situated beside the meatal opening, is not uncommon; it usually clears up under chemotherapy. If not, it may have to be dealt with by electrocautery or surgically.

Folliculitis (inflammation of Littre's glands), infiltrates, and peri-urethral abscess usually occur somewhat late and in maltreated cases, and may call for the use of Kollmann's dilator or intra-urethroscope treatment such as cauterization or incision.

Posterior urethritis probably occurs in a large proportion of those cases which are not treated in the early stages. It usually presents no special symptom; when it does, frequency, strangury, or even retention of urine may occur. Treatment consists of hot baths and suppositories of morphine, gr. 1/4, and atropine, gr. 1/70, one each night for a few nights; rarely it may be necessary to pass a

soft rubber catheter to relieve retention, but this should be done only as a last resort and with the strictest aseptic precautions.

Epididymitis occurs in about 5% of cases, and can usually be avoided if the patient leads a sedentary life during the acute stage and wears a jock-strap or sports slip. It may be caused by external violence such as a blow, too strenuous exercise, unskilled instrumentation, or over-forceful irrigation. In the acute stage the patient should lie up, the testicles should be supported with cotton-wool and bandage, and ice-packs or glycerin of belladonna or kaolin poultices applied. It usually clears up rapidly under chemotherapy; if it does not, puncture with an intramuscular needle often relieves the acute pain. Irrigation, if being given, should be stopped during the acute stage. Epididymitis is usually preceded by prostatitis and vesiculitis, and these should be dealt with when the condition has subsided. The vas deferens on the affected side is usually permanently blocked, so that if the condition is bilateral the patient is likely to be permanently sterile.

Prostate-vesiculitis.—This probably occurs in all cases of posterior urethritis and almost always precedes an epididymitis or arthritis. If acute it usually resolves under chemotherapy, but if it persists sedative treatment by means of hot sitz baths and morphine-and-atropine suppositories is indicated. A prostatic abscess generally bursts into the urethra, but may require surgical incision. In the chronic stage, when the only evidence is pus and perhaps gonococci in the secretions, regular gentle massage every 5 to 7 days and diathermy are indicated.

Arthritis and tenosynovitis usually attack one or two of the larger joints or the tendons around them—e.g., knee, ankle, shoulder, wrist; arthritis may also affect several of the smaller joints, such as those of the hands and feet. Treatment should be directed to the original focus—nearly always the prostate and vesicular seminales; artificial hyperpyrexia is very successful in early cases.

Cowperitis, keratoderma blennorrhagica, septicaemia, and endocarditis occur very rarely and call for the services of an expert.

Ophthalmia is rare in adults, and usually reacts very rapidly (within 24 hours) to chemotherapy. Protect the sound eye; instil atropine drops into the affected one and bathe frequently with boric lotion or sterile normal saline. Since ophthalmia may lead to permanent blindness it is wise to call in a specialist.

Test of Cure

If the patient has reacted well to chemotherapy, with or without irrigation, and if presumptive cure has been obtained by one or two courses of the drug within a week of discontinuing treatment, he should be re-examined once weekly for 3 weeks in order that any tendency to relapse may be detected, and then finally at the end of 3 months. *No lower standard of cure is permissible.* At the 3 preliminary weekly tests of cure the urethra should be examined for any discharge and the urine for heavy threads—i.e., those which sink within a minute. It is best to see the patient early in the morning after he has held his water all night. The presence of gonococci or numerous pus cells indicates incomplete cure.

Final Test of Cure

- Look for any discharge.
- Examine all-night specimen of urine in two or more glasses, telling the patient to retain some urine in his bladder. Make smears and cultures from any discharge or threads.
- Massage prostate and seminal vesicles firmly but gently with the patient in the knee-elbow position; expressed fluid should appear at the meatus. If it does not, tell the patient to pass the remainder of his urine: centrifuge this; make smears and cultures. Note condition of Cowper's glands before removing finger from rectum.
- Wash out urethra and bladder with oxycyanide of mercury lotion 1 in 8,000, leaving some in the bladder.
- Examine anterior urethra with the urethroscope for follicles, infiltrates, stricture, etc.
- Pass the largest curved sound which will traverse the meatus (say 22-26 Clutton) into the bladder.
- Tell patient to empty bladder.
- Take a specimen of blood for Wassermann, Kahn, or other serum test to exclude syphilis; have a gonococcal complement-fixation test done if the patient has been resistant to treatment or has suffered from complications.

If the patient passes all these tests satisfactorily he may be dismissed as cured.

Relapse

About 5% of all cases may be expected to relapse, and this is much more apt to occur in those cases which have reacted

poorly to chemotherapy. Treatment of a relapse is similar to that of the original attack, but tests of cure should be even more meticulous.

Summary of Treatment

1. Make sure of the diagnosis.
2. Before starting chemotherapy inquire for history of previous intolerance. No special diet is necessary.
3. Give sulphathiazole, 5 g. a day for 2 to 4 days, in evenly spaced doses; the drug need not be taken during the night. Give concurrent alkaline mixture and plenty of fluids. In place of sulphathiazole the following may be used: sulphadiazine, 6 g. a day for 4 days; sulphapyridine, 5 g. a day for 5 days; or sulphanilamide, 5 g. a day for 5 days. *Never give a sulphonamide preparation for more than 7 consecutive days in any circumstances.*
4. Look out for toxic effects of sulphonamides.
5. Look out for complications.
6. Always do a blood count before a second course of a sulphonamide.
7. Make certain that tests of cure are meticulously carried out: you cannot be sure the patient is cured unless you do. If he is not, he may unwittingly infect some innocent person.

Warnings

Cases are divided into two classes—those which are cured by sulphonamides and those which are not. Refer the latter to a specialist. You may regret it if you don't.

Don't give more or less of the sulphonamide than the dosage indicated above. If you overtreat, serious reactions which may endanger the life of the patient may occur. If you undertreat you may make the patient sulphonamide-resistant: he may then take months to cure.

Don't attempt procedures with which you are not familiar—e.g., irrigation, instrumentation, prostatic massage.

Don't use a syringe for intra-urethral treatment, and don't use provocative instillations for test of cure.

Gonorrhoea is a serious disease, and sulphonamides are dangerous drugs, not to be prescribed lightly.

The average V.D. patient is an unsatisfactory one; he is usually a liar. Tread very warily, especially as regards prognosis.

Appendix: Technique of Irrigation

Tell the patient to pass water.

Cleanse the glans penis with a little of the lotion to be used.

Use an irrigating vessel, preferably of glass, connected by a feet of rubber tubing to a blunt-pointed glass nozzle (anet type).

Pour two pints of the lotion at 100° F. into the container and expel air from tube and nozzle. Clip the tubing.

Adjust the height of the irrigating vessel not more than 6 feet above the patient's penis.

Patient should stand, or lie on an examination table.

Insert nozzle into the meatus, release the clip, and allow it to fill the anterior urethra. Repeat three or four times, allowing the urethra to empty after each filling.

Insert nozzle and tell patient to relax, take deep breaths, and pass water. In this way lotion may be coaxied into the bladder. Don't force it.

Repeat this procedure two or three times.

GONORRHOEA IN THE FEMALE

Treatment of this is carried out on similar lines to that in the male. Chemotherapy in proportionate dosage, making allowance for weight, is usually successful provided there are no closed foci—e.g., Bartholin's. Douching is to be deprecated; dry swabbing or swabbing with weak alkali is usually preferable. Skenitis, Bartholin's, cervicitis, and salpingitis should be dealt with as they occur, preferably by a specialist. Tests of cure should be carried out immediately after the menstrual period for 3 consecutive months following termination of treatment. They should include both microscopical and bacteriological examination of all pathological specimens and, of course, blood tests.

Medical Memoranda

Intestinal Obstruction after Caesarean Section for Contracted Pelvis

Cases of intestinal obstruction after Caesarean section reported up to 1938 are not numerous. O'Connor (1934) had one death from intestinal obstruction in 436 cases of Caesarean section, the patient dying on the sixth day. No suggestion was made as to the aetiology, except perhaps toxæmia. Haultain *et al.* (1933-4) found that irregular action of the bowels was present in 24 patients (14.1%). The lax post-partum abdominal musculature, arising *de novo*, was the only aetiological agent suggested. Montgomery (1936) considered peritoneal adhesions a possible cause of intestinal obstruction after Caesarean delivery, but he does not mention the possibility of pelvic impaction of the uterus. Quigley (1937) reported three cases of intestinal obstruction in a total of 358 Caesarean sections simply as "ileus," with one case—"Intestinal Obstruction: Operation."

The following two cases, treated shortly after each other in 1930-1, aroused my interest at the time. Search of the literature, however, failed to disclose reports of any similar case, although some must surely have occurred. Both women were primiparae under 30. Gestation had been normal so far as was known; there was no evidence of toxæmia and no history of renal disease. In neither had there been any previous laparotomy and no abnormality in the serous layers was observed at operation. Both were unbooked cases, admitted with obstructed labour.

CASE I

A. B., aged 19. Admitted to hospital on July 26, 1930, five hours in labour. No descent; Müller's test showed marked overlap of the anterior symphyseal border; P.V., sacral promontory readily felt. Classical Caesarean section was performed the same day under chloroform-open ether. A 7½-lb. full-term living male child was delivered. Closure was carried out in layers without drainage. Convalescence was uneventful, but there had been no bowel action by the third day. The patient then began to complain of distension and colic. The next morning she looked toxic and dehydrated, and had started vomiting. On rectal examination a large smooth rounded mass was felt, firmly fixed in and filling the true pelvis. It was concluded that this was the involuting uterus, which had become retroverted and impacted in the pelvis. It was therefore decided to reopen the abdomen.

On reopening through the original incision the uterus was found firmly impacted in the pelvis, and the pelvic colon in the region of the pelvic-rectal junction was very congested and flattened. It was decided to perform a colostomy. A Paul's tube was inserted in the transverse colon. The uterus was then fixed with a catgut suture to the anterior abdominal wall. The obstructive symptoms passed off and the colostomy was closed four weeks later.

It may be said that at the time of the Caesarean section there had been no evidence of saccululation of the uterus, indicative of a retention earlier in the pregnancy.

CASE II

C. D., aged 26. Admitted to hospital on June 9, 1931. 6½ hours in labour, which was obstructed, as in Case I, with gross pelvic contraction. The anaesthetic and the procedure were as in Case I. A 8-lb. full-term living male child was delivered.

In this patient convalescence was from the first somewhat stormy. There were early symptoms of chest complications, but, on the other hand, in the first day or two flatus was freely passed, and no tension was observed. On the third day, however, she vomited. Vomiting continued, and she became greatly dehydrated. The measures were adopted without improvement. A rectal examination on the morning of June 13 again revealed a large mass impacted in the pelvis. By this time, however, the patient was very toxic, and furthermore, the chest condition had developed in a manner strongly suggesting embolic phenomena. Operation being unfortunately not feasible, the patient died the next day. No necropsy was allowed but that the mass felt was the post-partum uterus I have no doubt.

The close resemblance between this and the preceding case struck me forcibly at the time, and I felt that prophylactic ventrifixation, as employed in the first case, would have prevented the post-partum uterus falling into the contracted pelvis and obstructing the colon. I have adopted the practice ventrifixation after Caesarean delivery in all cases since then and no symptoms of obstruction have occurred in any of the

DISCUSSION

In both cases Caesarean section was performed for marked pelvic contraction. Even if a post-partum uterus were to become retroverted and fall into a normal pelvis there would be sufficient clearance to prevent its becoming impacted. In the Caesarean operation the uterus is firmly compressed manually. Perhaps, in so doing, it is made small enough to fall into the contracted true pelvis, given that the latter is grossly contracted.

Whatever is the precise pathology, I am convinced that in both these cases the cause of the obstruction was the phys-

ness of the retroverted post-partum uterus impacted in the (contracted) true pelvis.

OBSERVATIONS

Impaction of the retroverted post-partum uterus in the contracted true pelvis has never, so far as I have been able to determine, been quoted as a cause of intestinal obstruction after Caesarean delivery.

Having seen it occur twice, it has seemed wise and logical to perform prophylactic temporary ventrifixation in all my subsequent cases of Caesarean section. Since adopting this practice I have seen no suggestion of obstructive symptoms in any of these cases of Caesarean section, some 20 in number. It would be absurd, however, to argue from two or twenty cases.

The mechanical obstruction I have described may be operative in a proportion of cases hitherto diagnosed as post-operative ileus." Spontaneous remission would of course be expected in most cases, as the uterus involuted.

I am much indebted to Mr. T. J. Shields, the B.M.A. librarian, for supplying the references to this paper.

Pediculosis Capitis and Corneal Lesions

The object of this memorandum is to draw attention to the frequency of severe corneal lesions associated with pediculosis capitis. It is a summary of observations made on 25 patients admitted to hospital for corneal lesions. I have been unable to trace any similar condition mentioned in the literature available to me, and I should be interested to know whether this observation has been made elsewhere.

It is, I think, a matter of common experience in wartime to find an increasing number of out-patients infected with lice. These observations were made in the out-patient department of the Infirmary during the last six months, with an average 200 patients a day. These infected patients, who came to us for eye consultation, were mostly young children, well fed, without apparent signs of general debility. The presence of lice, which were invariably *Pediculus capitis*, was discovered by chance on examination or later in the wards after admission. We could never find any phthiriasis palpebrarum, and the cilia were always unaffected. Apart from the conjunctivitis which was always present, the majority of cases had corneal ulcers (14 cases), 8 cases marginal keratitis, 1 case hypopyon ulcer, and 2 cases severe conjunctivitis without corneal lesion. The age incidence was as follows: 20 patients under 10 years and 5 patients over 10 years. The oldest patient was a woman aged 30. The Wassermann reaction was negative in all but one case.

The patients usually complained of burning pain of short duration in one eye, which gradually became worse and was accompanied by photophobia. The lesion was always unilateral. A severe conjunctivitis with some muco-purulent discharge was invariably present. Bacteriological examination of the conjunctival sac showed nothing characteristic; diphtheroid bacilli, streptococci, and staphylococci were present in some cases.

The corneal ulcers had no special features; they were central or paracentral infiltrations in the substantia propria with loss of epithelium. The marginal keratitis consisted of multiple subepithelial infiltrations with a quick tendency to break down and to form confluent paramarginal crescentic ulcers. In some cases they were confined to one side of the cornea only; in other cases they tended to spread all round the corneal margin, thus forming a more or less complete ring of infiltration. Slit-lamp examination showed infiltration of the anterior part of the substantia propria. Iris irritation was often present, but no K.P. or posterior synechiae were ever observed. Although this condition is very similar to the metastatic marginal ulcer of Fuchs, it showed but little tendency to respond to the routine treatment. In fact, it took a long time to heal, during which period the eye remained very congested.

The routine treatment was a sassafras cap for the head, carbolic of the ulcer, atropine 1%, argyrol 10%, sulphapyridine or uleron tablets, and protein shock (milk injections).

It seems probable that lice infestation causes not only conjunctival irritation but lowers the vitality of the cornea, resulting in severe corneal infiltration with little tendency to heal.

My thanks are due to the honorary surgeons of the Wolverhampton and Midland Counties Eye Infirmary—Mr. G. F. Haycraft and Mr. H. Campbell Orr—and the assistant surgeon, Mr. A. W. Green, for permission to publish this memorandum.

ARNOLD HIRTENSTEIN, M.D. Prague.

Wolverhampton and Midland Counties Eye Infirmary.

Reviews

THE CAMPAIGN AGAINST TUBERCULOSIS

The Modern Attack on Tuberculosis. By Henry D. Chadwick, M.D., and Alton S. Pope, M.D. (Pp. 95. 6s.) New York: The Commonwealth Fund; London: Oxford University Press. 1942.

Drs. Chadwick and Pope detect in most works on tuberculosis a singular tendency to look on the disease as an isolated problem rather than as one of the communicable diseases in its total social and economic background. "Since enough knowledge is already available to make the eradication of tuberculosis possible within a few generations if the established techniques are effectively applied, they have set out to provide "a concise digest of the experience of many workers and of present-day practices in a form serviceable to the health officer and administrator." The attempt has been wholly successful, and we strongly recommend this little book to readers even in this country, and not only to medical officers of health but to tuberculosis officers and medical superintendents of sanatoria, who will find among its contents sound principles and common-sense conclusions that will act as salutary correctives to preconceived notions or those that are merely the fashion of the moment.

In the U.S.A. sanatorium beds have increased from 9,000 to 90,000 in 40 years. Tuberculosis in dairy cattle has been almost eliminated, and pasteurization is widespread. But, unfortunately, as in this country, little progress has been made in finding cases of early tuberculosis. In naming the essentials of a programme for the eradication of the disease, the authors therefore put first "a medical profession interested in the problem and familiar with modern methods of diagnosis and treatment." And they stress the importance of a knowledge of certain basic data before embarking on any sound anti-tuberculosis campaign. The various diagnostic procedures are critically examined, and the conclusion at the end of this chapter deserves emphasis: "Prompt diagnosis is important to the patient, to the family, to the community. Every suspected case of tuberculosis should be cleared of suspicion as quickly as possible by being proven innocent or guilty of harbouring the disease. Time-consuming observation by physicians without resort to all the diagnostic aids at our command is to be condemned and rated as a disservice to the patient that borders on malpractice."

The sections on the sanatorium as a means of control and treatment, and on case finding in the community, are no less interesting and no less well balanced. The authors hold that tuberculosis presents one of the hardest administrative problems that confronts the health officer. They emphasize that when an authority fails to provide enough beds it is committed to a plan that is wasteful, ineffective, and in the long run costly. "Half-way measures will not exterminate tuberculosis. A sanatorium bed should be available for every active case of tuberculosis regardless of the stage of the disease. Treatment that will benefit the patient and also serve to shield others by protecting them from infection is the real objective of case finding." And, to quote again from later in the book: "From the standpoint of case finding the shift in the age distribution of tuberculosis mortality means that greater emphasis must be placed on the examination of adult contacts and on mass examinations of groups subject to the highest risks, such as workers in hazardous industries and adults on relief rolls." Patients in ante-natal clinics should be among the first to be considered for mass examination; and a selection of other groups should be based upon actual incidence of significant tuberculosis, as demonstrated by preliminary sampling. The yield of mass examinations will vary directly with the incidence of tuberculosis in the area concerned, and in many parts of the U.S.A. this has already fallen to a point which makes the cost of mass radiography, relative to the number of cases found, prohibitive. From the last chapter, "A Community Campaign of Eradication," we choose one final quotation:

"Too often health officers have taken the 'what's-the-use' attitude in regard to tuberculosis. They have been content to make the record a mere bookkeeping chore and let the case rest there. The health officer should look upon tuberculosis as a communicable

sease that calls for his best efforts to assist the physician in obtaining adequate treatment for the patient, and the maximum protection for the public. His responsibility is the same whether the case reported is tuberculosis, diphtheria, or small-pox."

NOTES FOR THE REGIMENTAL M.O.

Notes for the R.M.O. of an Infantry Unit. By C. P. Blacker, M.D., F.R.C.P. Oxford War Manuals. (Pp. 77. 5s.) London: Oxford University Press, 1943.

In this little book Dr. C. P. Blacker crystallizes his experience as a medical officer for three years to a battalion of the Coldstream Guards. It is safe to say that nobody employed in a similar appointment can fail to find something useful in Dr. Blacker's notes. Obviously he knows all the ropes; further, in examining each of the many difficult problems involved in regimental medical duties he brings to bear a mental detachment that results in the advocacy of the most simple and the most efficient methods. His advocacy of decentralization—a virtue that is only gradually permeating the Army—is admirable, not only does its adoption permit the medical officer to devote more time to more essential work but it also increases the efficiency and enthusiasm of those to whom he delegates responsible tasks. Subsequent chapters cover every aspect of a regimental officer's work, including that important part of it so close to many—the proper keeping of records and an efficient office routine.

There can be little doubt that Dr. Blacker was in a better position with regard to his unit than a young and newly commissioned medical officer. High professional qualifications, mature age, and a record of distinguished combatant service in the same regiment during the last war must have given him a standing attainable by few. But those who follow his precepts will surely benefit both themselves and the men under their care. The reader's heart warms to the author because he writes as was presumably the case—the humble, though most important, rôle of regimental medical officer, and because he dedicates the book to two sergeants of the battalion "in attitude for their unfailing help and loyalty."

OXYGEN THERAPY

Manual of Oxygen Therapy Techniques, including Carbon Dioxide, Helium and Water Vapor. By Albert H. Andrews, jun., M.D. (Pp. 191. 51.75 or 11s.) Chicago: The Year Book Publishers, Inc.; London: H. K. Lewis and Co.

This little manual restricts itself to a description of the technique and armamentarium of oxygen therapy. In so doing it becomes a handbook that will be invaluable to both medical and non-medical personnel who have to deal with oxygen therapy apparatus. Cylinders, reducing valves, tents, and masks are all fully described, and detailed descriptions of their use and maintenance are given. There is a most timely chapter on the safety precautions which should be taken whenever oxygen in quantity is used. Instruction in these precautions is now a part of every nurse's training, and much of this might well be reprinted and hung upon every bed where oxygen is being administered. That accidents do not so frequently occur is more a gift of chance than the reward of knowledge. Many of the figures concerning the sizes and capacities of cylinders and reducing valves apply to American types, and this data should be substituted by readers in this country. The use of helium-oxygen mixture and of mechanical humidifiers is described; but the more recent types of oxygen metering devices, developed in this country, are not mentioned. Dr. Andrews's book is well produced, with excellent illustrations, and is a model of clear and concise wording.

Notes on Books

The third edition of *Essentials of Materia Medica, Pharmacology and Therapeutics*, by R. H. Micks, is published by J. and A. Churchill at 16s. The considerable advances in therapeutics during the last five years have called for large alterations in the content of this manual of pharmacology, which presents in a condensed and easily accessible form the principal requirements of the student and the general practitioner. Prof. Micks avowedly deals only with the practical applications of the subject, and in his own words sets out to teach rather than to expound it. This is unfortunate, because though his book is of value for reference, the student coming to the subject for the first time will not find it easy reading. It is a pity

that such an artificial distinction is drawn between sulphanilamide and the other sulphonamides; it would seem more reasonable to classify these drugs from the start according to their bacteriological activity. But these and other minor points depend more or less on personal preferences, and the book as a whole bears the imprint of a practical human experience with materia-medica which makes it a useful accessory both to the student and in the consulting-room.

As Dr. J. J. CONYBEARE truly says in the preface to the sixth edition of his *Textbook of Medicine* (E. and S. Livingstone), one of the greatest problems before the editor of a work with numerous contributors is to prevent a progressive increase in the size of the book. With loyal co-operation all round the number of pages is practically the same as in the fifth edition, though under varying conditions the price has had to be raised to 28s. The sections on tropical diseases and on vitamins and deficiency diseases have been completely rewritten. The same may almost be said of the sections on tuberculosis and on diseases of the respiratory system, to which is now added a chapter on the treatment of wounds of the chest. Other sections which have grown are those on polyneuritis, common skin diseases, and on matters relating to blood transfusion. Dr. Conybeare's textbook in its latest version will make many new friends among final-year students and practitioners.

A new edition of *Aids to Surgical Anatomy* has been prepared by Mr. J. S. BAXTER, University of Bristol, who has revised, added and in part rewritten certain sections of the book in order to adapt it to modern concepts and to meet the requirements of senior students who are preparing for their final examinations. The manual, although small, contains a large amount of essential anatomical and surgical information, given in a form which serves to indicate the surgical significance of many simple anatomical facts which would otherwise be of merely topical interest. The illustrations are simple and serve the primary purpose of giving a visual impression of the structures described in the text. Some are, however, too diagrammatic, and in certain details are misleading with regard to the exact relative position of the parts depicted. This might well be replaced in future editions by simplified drawings made from actual sections of the parts represented; and also a few textual errors which have escaped the notice of the reviser might be rectified at the same time. The text is, however, remarkably free from error, and in these days when brevity is a necessity, a short book of this type should help senior students at the try-out period which precedes their final examinations. It is published by Baillière, Tindall and Cox at 4s. 6d.

The late RICHARD C. CABOT's *Physical Diagnosis* was first published in 1900 and went through eleven editions in 34 years. In 1937, when a more complete revision of the whole work was required, the author asked Dr. F. DENNETTE ADAMS to undertake the task. The text was thoroughly revised and enlarged in the twelfth edition; now a thirteenth has appeared, and once again Dr. Adams has drawn freely on the experience of colleagues at the Massachusetts General Hospital. Like its predecessor, this edition may be said to represent so far as possible a cross-section of the views on diagnosis held by the staff of that world-famous institution. Dr. Cabot died on May 7, 1939, and his name is rightly preserved in the main title, side by side with that of his collaborator and successor. The book now comprises 900 pages printed in good type with many clear illustrations among the text. It is published in this country by Baillière, Tindall, and Cox, price 27s. 6d., and will surely attract many new readers who feel a need for some guidance on diagnostic methods and processes.

Among numerous small cards and leaflets on the principles of first aid, one that deserves special mention is being sold at a price (1d. each, or 6s. a 100) by Dr. BERYL HARDING (16, Drayton Gardens, S.W.10). On a folder which, when doubled, is the size of an identity card, she has set out brief and succinct instructions for the first-aid treatment of fractures, wounds, burns, and shock, together with diagrams showing the pressure-points and the application of a tourniquet—which, Dr. Harding points out, is a dangerous weapon. The sensible balance of the leaflet may be judged from the opening sentences: "First aid is mainly common sense. It is better to do too little than too much. First aid properly applied saves lives and stops panic. Bad first aid may do serious damage and even lose lives."

The second edition of R. A. FISHER and FRANK YATES's *Statistical Tables for Biological, Agricultural, and Medical Research* contains four new tables and extends one of the tables in the first edition. The great value of the work is testified by the appearance of a new edition. Were a biological statistician confined to the use of a volume he would probably choose this. It might easily form part of a service equipment. The publishers are Oliver and Boyd and the price is 13s. 6d.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JULY 17 1943

BEFORE THE WHITE PAPER

The discussions between the Representative Committee and the Ministry of Health, which have gone on over the past six months, are now coming to an end. In these discussions the committee had no powers of negotiation and no mandate to commit the medical profession to any new policy. The function of the committee was to assert the point of view of the doctors of this country, and this it has done in an unequivocal manner. The twelve medical organizations represented on the committee will now in confidence report to their own bodies the gist of what has taken place. And among these the Council of the B.M.A. will receive such a report at a special meeting to be held on July 28. After that the Council will issue for the consideration of Divisions, early in August, a statement of what it considers to be the basic principles which should underlie the organization of the medical services of the country. The Annual Representative Meeting will assemble on Sept. 21 to 23 to consider these principles in the light of the discussions that have taken place at Division meetings. It is possible that by that time the Government will have published a White Paper on the provision of a medical service to the nation which will satisfy the proposals arising out of Sir William Beveridge's Assumption B. The White Paper will have to be examined with care and deliberation before the medical profession formulates its views on it. It will therefore not be on the Agenda for the A.R.M., for it should first of all be discussed by the Divisions, by Council, and subsequently by a special meeting of the Representative Body. When the views of the B.M.A. and other medical bodies and organizations are declared, a Negotiating Body will be set up to thrash matters out with the Ministry of Health. The situation, then, can be looked upon as falling into three phases. The first and present phase is to be given to the re-formulation of fundamental principles. In the second the White Paper will be examined and appraised. The third phase will be negotiations with the Ministry.

The inadvertent disclosure of the contents of a Ministry of Health memorandum showed that the lines along which the Ministry was thinking diverged sharply from certain principles which the medical profession holds, and holds firmly. At a moment when discussion groups—and in particular the Medical Planning Commission—were looking into the question of health centres, the Ministry confused the issue by linking on to this idea one that is abhorrent to the profession at large—namely, a whole-time State salaried medical service, with the doctor employed in the centre by the local health authority. The first principle, then, of any future reorganization of medical practice is that this should not be based upon a concept of a whole-time State salaried medical service. As Dr. Charles Hill, whose address to a recent meeting at Ipswich is printed elsewhere in this issue, points out, a whole-time salaried service may be a most appropriate form for certain kinds of medical work—for example, the control of environmental health by the public health service. It seems clear, too, that as a rule the whole-time research worker must live on a whole-time salary and with a background of security. But doctors in general challenge the view that the intimacies of family practice can be entered into by an

employee of the State or of a local authority. Bound up with this is the question of free choice of doctor. There is an attempt to decry this, and largely by those who have had no experience of private practice. The doctor employs techniques but is not a technician, and in fact the precise technical aid which he can give to his patient is very limited. What matters most is his quality as a human being in relation to another human being, and the fitness of this quality in any one case is something that only the patient in need of his help can judge. Such matters as this are alien to the administrative mind, which moves neatly and precisely in a world of time-tables and administrative buildings.

For years doctors individually and collectively have cried out against the crippling effects upon health of damp, crowded, and ill-ventilated houses, against lack of food and against food that is bad in quality and bacteriologically contaminated. The medical profession cannot be expected to hold in high regard a Ministry of Health which tolerates the spread of disease through infected milk. A profession which is not controlled by such a Ministry can freely voice its criticism and its policy in this and in other respects. We lay it down as another principle that the provision of good food, houses hygienically built, facilities for games, rest, and recreation in the open air, sound education in ways of thinking, will all promote the health of the public far more than will a reshuffling of the medical services. First things should come first. Medicine progresses not by an increase of authority or of authorities, not by the issue of regulations, but by increase and application of knowledge. Fundamental to this are medical education and medical research—and the State provision for medical research amounts (if we may hazard a guess) in one year to approximately the same sum as the Government has recently spent on Press campaigns against two infections. Another principle firmly held for years by medical men is that lack of money should not prevent a sick person from receiving medical aid when in need of it. Doctors have recognized this by giving their services without pay on the one hand, and by advocating the extension of National Health Insurance so as to include 9/10ths of the population on the other—an advocacy which has so far fallen on deaf ears. As to reform of existing services, the medical profession has been more progressive in its demands for this than has the Ministry of Health under a succession of Ministers of varying political colour. Another of the principles which the profession maintains is the need for thorough reform of both central and local health departments. The function of the State, as Dr. Hill points out, is to see that a comprehensive health service is provided. But it is not the duty of the State to control doctors on the basis of an employer-employee relationship. Most medical men in this country are opposed to the socialization of medicine.

These briefly are some of the major principles held by the medical profession. We feel sure that the Minister of Health is too good a democrat to wish to impose upon a profession that has no reason to be ashamed of its record a form of service that denies to practising doctors that freedom of professional action and initiative which they believe deeply to be indispensable to good work. That in some instances this freedom may be abused is a criticism not of the principle of freedom but of human nature. It is hoped, therefore, that the Government White Paper will be restricted mainly to exposition of the issues to be discussed, and that these issues will not be prejudged in set proposals, however tentative, to which in the main the Government may declare itself committed. It is hoped, too, on more than one ground, that the Government will be scrupulous not to take advantage of the abnormal

conditions in which we now live by putting a loyal and patriotic body of men in a position of having to oppose a National Government in time of war. We gravely doubt the wisdom of making in time of war any cut-and-dried plan for the conduct of medical services in time of peace—that is, if peace is regarded as the normal background of national life. To try to settle such a large issue in an atmosphere charged with the emotions of war would be unjust to both the medical profession and the public.

H 11 FOR CANCER

About two years ago many members of the profession received through the post a circular advertising a commercial preparation called H 11 for the treatment of cancer. The discoverer of the preparation is Mr. J. H. Thompson, B.Sc. It consists of an extract of urine and is described as "a concentrated preparation of growth-inhibiting substances which are normally present in the body." Many practitioners have used, and doubtless are still using, the preparation. In this issue of the *Journal* we publish two articles dealing with the matter: one by Mr. H. A. Kidd, who has treated 51 cases of cancer in human beings; the other by members of the Scientific Staff of the Imperial Research Fund, who have tested the preparation on tumours of mice. Neither article supports the claims made for H 11. So that we may be clear what these claims are it is as well to describe those coming from the laboratories where Mr. Thompson works: "Tumours in mice may either entirely disappear or be replaced by small fibrotic masses." Under the heading of "Clinical indications" the following statement is made: "Various types of cases of advanced inoperable carcinoma treated with H 11 extract in hospitals and private practice have resulted in marked reduction in size of both primary and secondary growths, and eventual disappearance. It is therefore a useful form of therapy in cases of cancer inoperable by other recognized forms of treatment. Approximately 70% of cases have shown objective signs of improvement." It is recommended that treatment with H 11 should not replace treatment by operation and deep x-ray therapy when these are considered by expert opinion to be applicable.

Of 51 cases treated by Mr. Kidd 14 received insufficient treatment, and of the remaining 37 patients 11 are dead, 10 have no reply was received from 5. Of the 21 patients known to be alive 4 have been under observation for under a year, 12 for over one year, and 5 for over eighteen months. Experienced practitioners are well aware of the difficulty of assessing the value of any treatment of cancer in human beings, and all would agree that 18 months is too short a time to reach a firm conclusion that a treatment is of use. Mr. Kidd's experience is hardly likely to encourage doctors to use H 11, especially as therapeutic experiments in human cases are beset with difficulties. Tests on animals must be arranged in accordance with scientific principles. A series of tumours of one kind, all starting on the same day and growing at the same rate, can be provided; proper controls can be set up and animals killed at regular intervals to determine whether the treatment has had any effect on the growth of the cells of the tumour. Using the large resources of the Imperial Cancer Research Fund in this manner, Prof. Gye and his colleagues have been unable to detect any inhibition of tumour growth in animals treated with H 11.

Mr. Thompson began his researches some 12 years ago with the dangerously seductive idea that cancerous growth is merely excessive physiological growth, and that inhibition of growth is brought about by a hormone

located in the parathyroid bodies. The difference between normal physiological and malignant growth was apparently regarded as quantitative and not qualitative, a mistaken view which is often assumed to be true in current literature and which is completely disposed of by mere reference to the growth of an embryo and the slow growth of many cancers. The unique nature of new growths—the unlimited character of the growth, the fact that the stimulus to multiplication of the malignant cell lies within the cell itself, and the failure of the forces which control physiological growth to control cancerous growth—does not seem to have been taken sufficiently into account by Mr. Thompson. That this is not a harsh or unwarranted judgment is well shown by the way in which the supposed value of H 11 is estimated: "The degree of inhibition produced by H 11 extract diluted nearly 5,000 times on the root growth of selected oat seedlings grown under strictly controlled conditions is measured, and the value of the extract adjusted to equal that known to cause regression of Twort carcinoma in mice." It needs no special knowledge or perspicacity to be aware of the fallacy both of correlating the growth of oat seedlings with the growth of cancer and of assuming that normal physiological growth would be exempt from such a non-specific inhibition. If it were true that H 11 can actually inhibit growth in general, then patients injected hundreds of times over periods of months would certainly show some signs of interference with normal growth. Mr. Kidd's patient No. 26, for example, was injected 730 times; surely after a few weeks the patient must have shown some signs of inhibition of growth of skin and hair and of blood cells if H 11 has the property claimed for it. Long before the 730th dose was administered the general consequences of physiological decay would have been observed.

H 11 has been available to practitioners now for the past two years, and apparently practitioners up and down the country have used this preparation for their patients suffering from cancer. It has presumably been sold both as a scientific remedy and as a product which will bring in a financial return to those who undertake the ordinary business risk of manufacture and marketing. This is of course normal practice in this country, against which nothing can be said. Nevertheless during the past years, and especially since the formation of the Therapeutic Trials Subcommittee of the Medical Research Council, it has not been uncommon for manufacturers to submit for controlled clinical trial by responsible bodies products believed by preliminary research to be therapeutically beneficial. In fact signs of increasing co-operation between the pharmaceutical industry, research institutes, universities, and hospitals have been welcomed by the medical profession as it is of the great benefits to medicine to be expected when the vast resources of modern industry, its material, equipment, and scientific knowledge, are harnessed to the existing machinery for clinical research. We therefore regard it as unfortunate that a remedy believed to have the power of inhibiting growth was produced and marketed for the treatment of cancer in the absence of further controlled observations by men with special knowledge of the scientific and clinical aspects of cancer. We do not know where the fault lies, but the fact remains clear that after this preparation has been used by practitioners for two years examination of its properties in the laboratories of the Imperial Cancer Research Fund—one of the leading organizations devoted to cancer research—shows it to have no action on animal tumours. Neither are the claims made on behalf of the remedy supported by the clinical testing to which it has been subjected by Mr. Kidd at the Kingston County Hospital. Cancer is such a grave disease and is looked upon by the genera

public with such intense fear that anyone believing that he has a contribution to make to its relief or cure should regard it as his bounden duty to exercise the utmost scientific caution in making claims on behalf of a cancer remedy, however strong and sincere may be his belief in it. Practitioners similarly have to steel themselves against the natural impotency of sufferers and their relatives before yielding to the temptation to try something on the basis, say, that if it does no good at least it can do no harm. The harm that is done is by a raising of false hope.

HAEMOLYTIC MECHANISMS

The study of anaemia in man has switched for the moment from the field of nutrition to that of haemolysis. The increase in the practice of transfusion has focused interest on transfusion reactions. Mollison¹ has discussed the investigation of these reactions recently in our columns and has shown that they are usually due to mistakes in blood grouping, failure to maintain adequate standards in blood storage, or the use of Rh-positive blood for transfusion to recipients who have become sensitized to the Rh agglutinin. The discovery of the Rh antigen must be ranked as the most concrete gain from these and similar investigations. Some 15% of people have red cells which lack this antigen, and they therefore develop antibodies to it when they receive blood or are impregnated with a child which possesses it. Blood group incompatibility between mother and child, usually in relation to the Rh factor but sometimes to the normal A and B agglutinogens, is responsible for the grave anaemias and jaundice of the newly born. It is now proposed that these anaemias, with their sequels of "kernicterus" and fibrous dysplasia of bone, should be grouped together under the heading of haemolytic disease of the newly born.² The advance of chemotherapy has also led to an increase in haemolytic anaemia. By 1941 nearly 100 cases of haemolytic anaemia due to the sulphonamides had been reported in the literature.³ This appears to be an uncommon idiosyncrasy. It often happens, of course, that breakdown products of these drugs damage the haemoglobin molecule and change it to methaemoglobin. In certain individuals, however, products arise which damage the cell envelope and cause lysis. This metabolic error is persistent, and at any subsequent time a small test dose may induce haemolysis in the patient.⁴ The antituberculous drug promanide, which is related to the sulphonamides, much more commonly induces haemolysis, and it is so usual with the anthelmintic phenothiazine that it is unjustifiable to use it in man. These drugs are not themselves haemolytic *in vitro*, and it may prove a laborious task to discover the path—perhaps the final common path—by which haemolytic degradation products arise. Earlier studies are well summarized in von Oettingen's⁵ review of organic chemical industrial hazards to health, and some interesting results have recently been obtained by Emerson and co-workers,⁶ who have shown that several derivatives of these drugs and chemicals produce increased volume and fragility of erythrocytes *in vitro*. Perhaps there is a tendency to take too narrow a physico-chemical view of haemolysis, and more might be learned by thinking biochemically, in terms of ferments and their substrates—the method which has proved so fruitful in elucidating the mechanism of chemotherapy.

With other forms of haemolytic anaemia more progress has been made by studies *in vitro*, though understanding is still far from complete. We can demonstrate the actions of cold in syphilitic haemoglobinuria, acid in nocturnal haemoglobinaemia, and lysolecithin in acholuric jaundice. Until this year complete ignorance existed of the mechanism at work in the most important of all haemolytic anaemias, blackwater fever. Maegraith and co-workers⁷ have now presented evidence that the tissues normally contain a lytic enzyme, which is species-specific, and the serum contains an inhibitor, which is non-specific. Washed guinea-pig lung haemolyses a suspension of guinea-pig red cells, but the action is inhibited by guinea-pig or human serum in appropriate dilution. A method is therefore available for titrating the concentration of the inhibitory factor in the serum. They have subsequently shown⁸ that the activity of the inhibitory factor is reduced during the haemolytic crisis of blackwater fever. These results are important, not only because they imply a new technique for the study of blackwater fever but because it is possible that the acute haemolytic effects of chemical substances may be due to an interference with either the production or the action of the serum inhibitor.

GOITRE IN COUNTY TIPPERARY

The Medical Research Council of Ireland in its report for 1942 records that for several years it has supported an inquiry into the problem of goitre in the South Riding of County Tipperary. Attention was originally drawn to the prevalence there of colloid goitre by Dr. M. Naughten, county medical officer of health. The Council then arranged that Dr. J. Shee should visit Prof. David Marine of New York to study the methods used in the goitre areas of the U.S.A., with a view to making an inquiry on similar lines, including a survey to determine the incidence and severity of the condition and an investigation of the iodine content of the soil. In Tipperary the disease is not associated with cretinism or mental deficiency. Dr. Shee's survey revealed that goitre was present in about 50% of the school children in certain districts. The estimation of iodine intake and output presented a more difficult problem. Preliminary investigation of the iodine content of foods by Dr. E. M. Mason did not disclose any gross deficiency, but a more detailed inquiry in Cashel Industrial School showed that though the health and development of the children were in all other respects highly satisfactory the incidence of goitre approached 90%, and this was associated with a low intake of iodine: the iodine output was nil. In the Council's experience the results of iodine treatment have not been dramatic, but a careful survey of individual cases did show an improvement, and there was also in some schools evidence of improvement which looked statistically significant. At this stage the situation was carefully reviewed, with an eye to decisions on future policy. As a result the investigation into iodine intake has been widened to include the intake under the ordinary dietetic conditions of the countryside districts of Tipperary where goitre is prevalent, and also other dietetic factors which might have a bearing on the problem. The Council has also instituted a scheme for thorough iodization, in a limited zone, with a view to determining the effect on the incidence of goitre; for this purpose Dr. Stephanie Whelan will direct the iodization of (a) pregnant women, (b) children before school age, and (c) school children in two goitre districts. The Council hopes, in four or five years, to be in a position to claim that by such measures

oitre can be suppressed in the coming generation. The whole work on this problem illustrates the need for long years in research, even where the investigation appears at first sight fairly straightforward. Acknowledgment is made of the help given by the Iodine Educational Bureau and its director (Dr. F. C. Kelly), Prof. J. Reilly, Dr. Naughten, and Dr. D. K. O'Donovan. Another inquiry during the year was into bacteriological problems arising out of a grave epidemic of diarrhoea and enteritis in Dublin. For these and other purposes grants were made to 25 individuals, and the report gives a summary of work done by grant-holders and a list of their publications.

A POINT IN E.C.G. DIAGNOSIS

The electrocardiographic (E.C.G.) changes in cardiac rhythmia and in coronary thrombosis have been well described and classified. E.C.G. changes of a less definite nature have often been rather loosely interpreted as indicating either myocardial disease or coronary sclerosis. Katz and others¹ have compared the post-mortem findings with the E.C.G. diagnoses in 149 consecutive necropsies. They have confirmed the specific nature of various E.C.G. patterns of right and left ventricular strain. These patterns are not the result of myocardial infarction, but are shown to be associated anatomically with ventricular hypertrophy. Myocardial infarction may, however, simulate these patterns. The authors distinguish a simple change in electrical axis (not commonly associated with cardiac abnormality) from ventricular preponderance—usually evidence of myocardial strain. More recently Katz and others² have noted E.C.G. patterns which are a combination of right and left ventricular strain. The absence of axis deviation in the presence of clinical and radiological evidence of cardiac enlargement is presumptive evidence of combined ventricular strain. They have described six patterns of combined ventricular strain: they are made up of QRS patterns of one type of ventricular preponderance with changes associated with hypertrophy of the other atricle.

This fresh conception of E.C.G. interpretation would be most helpful if it were not that myocardial infarction may cause similar patterns. It is not always easy to be certain in a particular patient that coronary thrombosis has not occurred—in fact, that may be the very point which the cardiogram is to decide. This is especially true in extensive heart disease. Sharpey-Schafer³ suggests that the problem may be solved by giving potassium by mouth; this, according to him, accentuates the T-wave inversion of myocardial infarction and tends to elevate inverted T waves of ventricular preponderance. It will be interesting to see how this cardiographic conception of myocardial strain stands the test of further investigation by other workers, and whether it is going to be of real value in diagnosis and prognosis.

THE V.D. PROBLEM IN CANADA

A report of the proceedings of the South-Western Canada Conference held at Edmonton in October, 1942,⁴ shows how the Canadian authorities are to the problem of venereal disease; their activities have led to a very considerable fall in the incidence of these diseases. One of the great problems has been brothels, and various resolu-

tions were passed calling for more active measures in dealing with them, their owners, and their inmates. Of other subjects discussed the more important were pre-marital blood tests, shorter and more intensive treatment of early syphilis, standards of cure of syphilis, status of serological tests for syphilis, diagnosis and treatment and standard of cure of gonorrhoea, and the liaison and co-operation between the Armed Forces and the civil authorities in finding and dealing with alleged sources of infection. Modern methods of treatment of syphilis all tend to shorten and intensify therapy, and when a short method which is also safe and effective is discovered it will prove a great advance on those hitherto practised. Recent advances in serology have shown how many pitfalls there may be in serum tests for syphilis, and more and more conditions both pathological and physiological are being added to the list of those which may give false positive reactions. Case-finding and contact-tracing occupy a prominent place in the discussions, and there can be no doubt that these procedures are likely to have a very salutary effect in reducing the incidence of venereal disease. Such a conference wherever held must do a vast amount of good in the way of both propaganda and education; the idea might well be copied by other countries, and an international one after the war has much to recommend it.

NEW REGULATIONS FOR THE F.R.C.S.

As explained in our Universities and Colleges column this week (p. 90) the Council of the Royal College of Surgeons of England has revised the regulations for the Fellowship, and these will come into force after the end of 1943. The changes embodied in the new regulations are possibly the most important that have been made since the Fellowship was instituted under the Charter of 1843. After Nov. 29 next the Primary Examination cannot be taken by undergraduates, and the subjects will be anatomy (including normal histology), and applied physiology and the principles of pathology. No candidate for the Final Examination will be admissible without producing evidence of having been engaged in the acquirement of professional knowledge for at least two years after obtaining the M.R.C.S. or some other qualification recognized by the Council of the College. A point to note is the rearrangement of the dates of the examinations, enabling those who are eligible, and who may wish to do so, to enter for both the Primary and the Final at the same time, on the understanding that should they be unsuccessful in the Primary their entry for the Final will be withdrawn and the fee paid for that examination will be refunded in full. All who aspire to the diploma of F.R.C.S.Eng. should write to the Director of Examinations, Examination Hall, Queen Square, W.C.1., for copies of the new regulations.

The Council of the Royal College of Surgeons of England on July 8 received with acclamation the announcement that Mr. Churchill had accepted the Honorary Fellowship of the College offered to him on the occasion of the celebration of the centenary of that Fellowship. All Fellows and Members of the College will share the Council's gratification.

In last week's *Supplement* it was announced that the Annual Representative Meeting of the B.M.A. would be held on Wednesday, Thursday, and Friday, Sept. 22, 23, and 24. It has been found necessary to alter this arrangement. The meeting will be held on Tuesday, Sept. 21, Wednesday, Sept. 22, and Thursday, Sept. 23.

A NEW METHOD OF GAS TRAINING

BY

POLLOK DONALD, M.B., Ch.B., D.P.H.

Teachers of first aid and "gas" know only too well that success is only to be obtained by constant repetition of essentials. Now, training has never been popular outside the lecture-room, possibly owing to the practical training necessitating a scattered personnel. Whatever the reason, the effect is that the personnel become bored and apathetic. To obviate this apathy we introduced a miniature method of gas training which enabled us to lessen the number of practices in the gas section and which, we found, overcame many of the drawbacks and at the same time proved interesting, educative, and even attractive.

In the reception-room of our first-aid post are a number of canvas screens. These were utilized to make partitions, as shown in the accompanying sketch, while forms were used for the front walls, the post being fully open to view. In short, the various sections of a gas post were linked up in miniature so that all could be seen and heard just as in a lecture-room. The whole can be rigged up in a few minutes. Some of the equipment is the same as in the gas post, but cotton reels are made to represent the shower-bath nozzles at the end of short lengths of rope, the latter, etc., being make-believe.

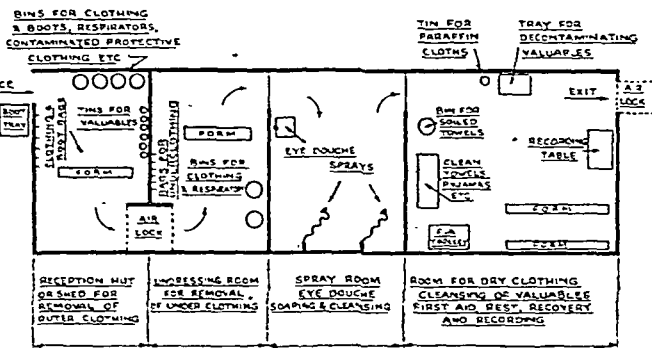

Diagram of miniature gas-cleansing station for demonstration and instruction.

The limit of undressing is that a jacket is removed in the first section to represent outer clothing, while a pullover or waistcoat is removed in the second section to represent underclothing. The dressing is carried out by merely holding the robe or pyjamas in front of the casualty, symbolical of having put them on. The personnel play the parts of casualties and operators. This is especially instructive, since the "casualty" must have a knowledge of the supposed lesions and the operator must know how to question and interpret. Moreover, such carried articles as respirators, helmets, handbags, metallic and paper valuables, crutches, etc., must be dealt with, and, since all are listening and observing, the practice becomes really valuable. We have certainly found it to work out this way, and I can confidently recommend it to those who have not tried it.

Fortunately we have had no experience of actual cases in this country. This, however, has created bands of theorists, so that each post doubtless has its own pet technique. So long as general principles are observed this makes little difference, provided the personnel know what to do and how to do it. The object of this communication is not to instruct but to show how instruction may be given in a way acceptable to all concerned. We do advocate, however, that practice be carried out in a thorough manner from entrance to exit. Slackness is most infectious, and is one of the primary causes of discontent.

LEPROSY RELIEF IN THE EMPIRE

At the annual meeting of the British Empire Leprosy Relief Association was held at the India Office, with the Duke of Devonshire, Under-Secretary for the Colonies, presiding. The annual report, which was adopted, mentioned the work which the medical secretary of the Association, Dr. E. Muir, has been seconded to carry out in the British West Indies, where he is assisting in the control of leprosy in Trinidad and other islands. His work there has coincided with the initiation of operations under the Colonial Development and Welfare Board, and he is in collaboration with the medical adviser to the comptroller, Sir Rupert Briercliffe, who has had experience of leprosy in other parts of the world.

Sir William Peel, chairman of the executive committee, said that he oversea workers whom the Association had sent out were stationed for the most part in Nigeria, the Sudan, and Tanganyika, and consisted of three doctors, fourteen "Toc H" workers, one nurse, and one lady lay worker. In Nigeria the incidence of leprosy was extremely high; the number of sufferers was estimated at over 100,000. In Northern Rhodesia the Governor had reported that the leprosy work already started there by certain missionary societies on lines suggested by Dr. Muir had proved satisfactory, and that his Government had made additional provision in Estimates to enable the work to continue on a more extensive scale.

The medical address was given by Major-General Sir Cuthbert Sprawson, and took the form of a review of the progress made during the 19 years since the Association was founded. He contrasted the leprosy asylum in India at the beginning of that time with what it is to-day. The care of the patients had greatly improved, the scientific classification of cases, their laboratory investigation and efficient treatment were now matters of routine, patients were kept usefully employed, and the atmosphere was one of hope, stimulated by the sight of many leaving hospital fit to return to the outside world. The improvements in treatment had included, in the first place, Sir Leonard Rogers's introduction of active derivatives from the oil and from various species of *Hydnocarpus* seeds, better methods of educating the native population on the disease and the proper mode of living for those who had contracted it, and increased knowledge of nutrition, malnutrition being a predisposing cause. The purely

laboratory side of research had, on the whole, yielded disappointing results, but the new leprolin and the iodide test had proved of value. In the matter of general hygiene more leper settlements and clinics were required, also separate institutions for those who had passed through the contagious stage but were too old or feeble to work, and who took up room in hospital which was wanted for cases needing more urgent treatment.

EUROPEAN ASSOCIATION OF CLINICAL PATHOLOGISTS

At a meeting of the recently formed European Association of Clinical Pathologists held in London the following officers were elected: President, Dr. S. C. Dyke (England); Vice-President, Prof. E. J. Bigwood (Belgium); Secretary, Dr. F. Pick (Czechoslovakia); Treasurer, Dr. B. L. Della Vida (Italy); Council, Drs. A. Benau (Yugoslavia), D. C. Canné (Netherlands), F. Duran-Jorda (Spain), Prof. F. Silberstein (Austria), Drs. G. Ungar (France), J. Ungar (Czechoslovakia). The annual subscription, including entrance fee, was provisionally set at 10s. The meeting adopted rules for the procedure of the Association while its members are mainly in this country, and instructed the Council to consider and report to a future meeting on the procedure to be adopted after the liberation of Europe. A resolution was passed to the effect that free interchange of workers in clinical pathology between the nations of Europe would be an important factor both in the advancement of scientific medicine and also in the development of a common European mentality, these being the main objects of the Association. The Council was instructed to explore the matter and report to a future meeting. It further invited the co-operation of the British Association of Clinical Pathologists in the project. A letter was received from the secretary of the B.A.C.P. inviting members of the European Association to participate in its gatherings.

Membership of the European Association is open to medically qualified men and women of all European nationalities engaged in any form of medical laboratory work. Those interested should communicate with the secretary, Dr. F. Pick, Department of Clinical Pathology, the General Hospital, Walsall, Staffs.

B.M.A. LUNCHEON TO OVERSEA MEDICAL SERVICES

A luncheon at which occasion was taken to welcome representatives of the medical services of the Dominions and Allies at present in London was given by the British Medical Association at the Savoy Hotel on July 6. The guests were received by Sir Beckwith Whitehouse (President of the Association), who was supported by the Chairman of Council (Mr. H. S. Souttar), the Chairman of the Representative Body (Dr. Peter Macdonald), and the Treasurer (Dr. J. W. Bone). The overseas guests included representatives of Canada, Australia, and New Zealand, of the United States, and of Belgium, Czechoslovakia, Free France, Holland, Yugoslavia, Norway, Poland, and the U.S.S.R., the last-named country being represented by Prof. Sarkisov.

Among other distinguished guests were the following:

Sir John Anderson (Lord President of the Council), Mr. Ernest Brown (Minister of Health), Mr. Thomas Johnston (Secretary of State for Scotland), Sir John Maude (Secretary, Ministry of Health), Sir Wilson Jameson (Chief Medical Officer of the Ministry), Dr. A. Davidson (Chief Medical Officer, Department of Health for Scotland).

Surg. Vice-Admiral Sir Sheldon Dudley (D.G., Medical Service of the Navy), Lieut.-General Sir Alexander Hood (D.G., Army Medical Services), Air Marshal Sir Harold Whittingham (D.G., Medical Service of the R.A.F.), Major-General Sir Ernest Bradfield (Medical Adviser, India Office), Prof. F. R. Fraser (D.G., Emergency Medical Service).

Lord Moran (President, Royal College of Physicians of London), Sir Alfred Webb-Johnson (President, Royal College of Surgeons of England), Sir W. Fletcher Shaw (President, Royal College of Obstetricians and Gynaecologists), Sir Stanley Woodwork (Master, Society of Apothecaries), Dr. C. McNeil (President, Royal College of Physicians of Edinburgh), Dr. J. H. Macdonald (President, Royal Faculty of Physicians and Surgeons of Glasgow), Sir Henry Tidy (President, Royal Society of Medicine), Dr. Cyril Banks (President, Society of Medical Officers of Health), Mr. S. T. Irwin (Chairman, North of Ireland Medical War Committee).

Sir Henry Dale (President, Royal Society), Sir Edward Mellanby (Secretary, Medical Research Council), Sir Malcolm Robertson (Chairman, British Council), Sir Hugh Lett (Chairman, Committee of Reference), Sir F. E. Fremantle (Chairman, Medical Committee of the House of Commons).

The guests also included former holders of high office in the Association (Lord Dawson of Penn, Sir Kaye Le Fleming, and Dr. H. Guy Dain, former President, Chairman of Council, and Chairman of Representative Body respectively), the Chairman of the Metropolitan Counties Branch (Sir Crisp English), and the chairmen of the various headquarters committees.

"Allied Medical Services"

After the toast, "His Imperial Majesty," had been proposed by the PRESIDENT and duly honoured, Mr. H. S. SOUTTAR submitted "Allied Medical Services." He said that the profession in Great Britain welcomed these comrades in a struggle upon the issue of which depended all that they held dear. The profession was a brotherhood to fight against disease, and the Allied nations a brotherhood to fight against the devil. Doctors had an interest in both quarrels, and would be satisfied only with a double victory. He referred to his experiences during his recent visit to India, and especially to the medical services in hospitals which he saw in North-Africa. It was inspiring to serve the energy and vigilance which were maintained with the smoothness with which the Imperial Forces and those of the Allies all worked together, in the furnishing, for example, of mobile surgical teams with every possible equipment, in the use of the great ambulance planes, and in the provision of blood banks and other life-saving and health-storing measures. But great as had been the difficulties of the African campaign and high as the achievement of its medical services they were left marvelling at the difficulties and achievements of Russia, whose representatives they saluted at that occasion.

The toast was responded to by Brig.-Gen. PAUL HAWLEY (I.S.A.), who said that the welcome given in Britain to the Allies had been most cordial. One of the few agreeable experiences in this war was the opportunity which it had afforded to the medical professions of the Allied nations to associate with one another. In peace their leaders had always sited back and forth, but the opportunity of such association had come rarely to the rank and file. The rank and file of the American profession were now learning something during their sit here, and they fondly hoped that in their turn they might have behind them two or three useful ideas when they returned home. Many of the landmarks in the history of medical science had come about through the achievements of the ordinary

worker. Sir William Osler once said that the greatest contribution that America had made to physiology was the work of William Beaumont,* a very undistinguished Army surgeon stationed in a veritable wilderness. It might be given to some member of the rank and file now serving far from home in the Army to make a similar contribution.

The Lord President on "Medicine"

Sir JOHN ANDERSON, in proposing the toast of "Medicine," mentioned his own official responsibility, as Lord President of the Council, for medical research and indeed for research of all kinds. When research was mentioned in connexion with this war people thought inevitably of the perfection of the engines of destruction, but he was glad of the opportunity of calling attention to the fact that in quite another field—that of the health, comfort, and well-being of the Armies and of the civil populations—science had made a contribution no less conspicuous and spectacular. They were all aware that in the great campaigns of the nineteenth century disease took a toll far exceeding that taken by the enemy. In the South African War more men died of disease than of wounds. In the first European war the troops were beginning to receive the benefit of the advances in medical science which had been made in the early years of the century, especially in the field of bacteriology. Since then there had been further progress. It was gratifying to learn that when a considerable number of German and Italian prisoners came into our hands in North Africa and were found to be riddled with disease—typhoid and dysentery—our medical men who set to work upon them with the resources at their disposal showed conclusively that for example, the T.A.B. vaccines with which our own people were supplied were infinitely superior to what had been supplied by the enemy. With the resources for combating infection available to British medicine these infections among prisoners of war were being cleared up in a remarkable way. A great new range of therapeutic agents had been made available by the devoted work of biochemists on the sulphonamide compounds, which had completely revolutionized the treatment of infective conditions. He had lately been told of new uses found for these agents as a result of which the treatment of septic conditions, so fruitful a source of illness and death, had been completely reformed. These great advances were due to the work of men who had laboured for the most part anonymously, or at least obscurely, in various laboratories.

But it must not be supposed, Sir John Anderson continued, that they had reached the end of their problems. He was told that the problems presented by cases of traumatic shock were still most baffling. He could never forget, having spent some years of his life in India, that the problem of malaria in eastern regions and in the islands of the Pacific and Indian Oceans (as had been shown again in Madagascar) taxed the utmost resources of medical science. A complication here was the loss of the main sources of the production of quinine, but much work was being done to make good the deficiency by the production of new synthetic drugs, in which American manufacturers were actively collaborating with our own, and he hoped that before long there might be adequate supplies of atabrin when quinine was not available.

Contributions not less important than these had been made along other lines of research. The Medical Research Council had been able by a close study of the conditions under which men served in tanks and aeroplanes to devise measures for ensuring their health and improving their comfort and efficiency in such environment. After the war hundreds of millions in Europe would be found suffering from malnutrition to an extent never before conceived. What would follow in the train of that malnutrition when vast movements of population took place, when armies were demobilized, and workers returned to their homes? It was a task which would call for the utmost endeavour and capacity, and he was glad to feel that in this prospective service medical men of all the Allied nations would collaborate. Two years ago, following a meeting at St. James's Palace, an organization was set up to deal with problems of European relief after the war. A medical committee had been established in connexion with that organization, and the

* William Beaumont (1785-1853), surgeon in the U.S. Army. Published in 1835 *Experiments and Observations*, dealing with the chemical nature of digestion, the significance of the gastric juice, and the causes of interruption of the secretion.

problems with which it would have to deal would demand the utmost that could be contributed collectively in knowledge and service. In associating with the toast the names of representatives of three countries, one of them Poland, he made a sympathetic reference to the tragic death of General Sikorski.

Three Responses

Prof. A. T. JURASZ (Poland) referred to his visit to this country twenty years ago, to the International Congress of surgery, and mentioned that the Congress was opened by the British Foreign Minister of that time, the late Lord Curzon, who confessed, as a man who had never had anything to do with doctors, how the atmosphere of such a medical gathering inspired him. But he added, "Gentlemen, Europe is very sick. Can you suggest a suitable operation to cure her?" Europe to-day was certainly more injured and diseased in every part of her organism than it was five years after the last armistice, and the principles of medicine might well be applied in the great task of reconstruction. The modern medical point of view comprehended not only the physical derangement but the mental and spiritual background. It was the psychical injuries inflicted by the aggressor upon helpless and suffering peoples that would call for the first attention, the most patient and understanding treatment. It would be well if political leaders themselves were imbued with the spirit and aims of true medicine.

Col. J. HOLST (Norway) told of a physician who, narrating he triumphs of internal medicine, said that presently it would become difficult to find a disease from which a patient could live or by which a surgeon could live. He was glad, as a visitor from another country, to have seen the spirit in which British doctors and the British people were responding to the demands of war. There were differences of opinion, he said, as to the new orientation of medicine, but in medicine as in life, while outward forms changed, fundamental principles remained.

Finally, Dr. J. B. MILLER, Deputy Chairman of the Representative Body, after entertaining the company with some student reminiscences, spoke of his pleasure in responding on behalf of general practitioners—the patient oxen who trod out the corn—as well as of the consultants and specialists who on occasion descended from the heights of Olympus to enlighten them.

NEW FIELDS FOR THE ALMONER

Two directions in which the social worker may find new opportunities were indicated by Prof. James Mackintosh of Glasgow in an address at the annual meeting of the Institute of Hospital Almoners. He pointed out that the almoner was now taking her proper place as a member of the company of healing, instead of being a mere assessor of finance, but she had yet to be brought into association with the teaching of medical students. At the Johns Hopkins Medical School the student in his third clinical year was sent for tutorial instruction for one or two hours a week at the almoner's office. The almoner took the student through some of her recent cases, showed him what was written about the diagnosis when the patient came in, what was ascertained on preliminary inquiry as to his social circumstances, and what requests for further information were made by the physician. Presently the student was sent out to some (carefully selected) homes, where he pursued his own inquiries, at first in a stiff and perhaps rather absurd way, but presently he gained the idea of what was meant by social work. A second field of opportunity, but a more vaguely defined one, was open to the almoner in connexion with general practice and the coming of the health centre. The Cathcart Committee in Scotland in 1936 recommended that the family doctor should be the health adviser to the family, but in existing circumstances the doctor was called in only in case of illness, and the present service of general practice was fundamentally a sickness service. On the other hand, there was the health visitor, who had her own special role, but was not trained in social work as the almoner was, and had not the time to undertake these skilled and delicate investigations. In psychiatry the social worker had already established her position, but as for general medicine Prof. Mackintosh was doubtful about the desirability, even if it were possible, of having almoners all over the country like health visitors and nurses. But he felt that the position of almoner might well be regarded as something like that of a health consultant. The future health centres or groups of practices might well employ almoners in a consultant capacity, so that the practitioners could refer to them cases presenting any special difficulty from the social point of view.

MEDICAL PRACTICE: IN THE MELTING-POT?

ADDRESS BY DR. CHARLES HILL

At a meeting at Ipswich on July 8 of the Suffolk Branch of the B.M.A., Dr. Charles Hill, Deputy Secretary of the Association, spoke on "Medical Practice: In the Melting-pot?"

There lay ahead of both the public and the medical profession, Dr. Hill said, a critical period, in which decisions of profound importance to the future of medical services would be taken. So far the Government had committed itself to Assumption B of the Beveridge report and so to a comprehensive health and rehabilitation service available to the whole of the community. It had stated its intention to administer that service through locally elected bodies. Within the framework of these two decisions informal discussions had been taking place between the Minister of Health and his officers, and representatives of the medical profession, voluntary hospitals, and local authorities. At the end of these informal and non-committal discussions the Minister would set out in a White Paper any tentative conclusions of the Government as a whole on the form that the proposed service should take. It was not yet clear to what extent this White Paper would be a statement of the issues or would include the Government's own conclusions. It was sincerely to be hoped that, on a matter of such profound importance to the public as a whole, the Government, by making this White Paper as non-committal as possible, would leave the crucial issues involved for free and frank discussion by the public before Parliamentary decision. It would be undesirable if consideration of these public issues began on the basis of commitments entered into by the Government beforehand. He hoped that the known political sagacity and wide experience of the Minister of Health himself would lead the Government to make a statement of the issues to be resolved rather than a premature, if tentative, expression of Cabinet opinion.

Fundamental Principles

The publication of the White Paper would be followed next winter by exhaustive and critical analysis of its contents by the profession, mainly through the Study Groups and Divisions, the Council and its Committees, and finally the Representative Body of the Association. Service men at home and over-seas would be given the fullest opportunity of expressing their views; but that, Dr. Hill pointed out, was Phase 2, and it would take time. Phase 1 should start now, and should be a clear and candid statement of the principles which should, in the public interest, underlie any future organization of medical services. The profession might well now divest their minds of details and search them for fundamental principles. The Council of the B.M.A., recognizing this position, would shortly be recommending to Divisions, and to the Representative Meeting to be held in September, a statement of fundamental principles. What, Dr. Hill asked, was really fundamental, in the public interest, to future development? He suggested certain points for immediate consideration.

The health of a people depended primarily upon the environmental conditions under which it lived: upon good housing, good food, adequate wages, and security against fear and want. No Government should be allowed to bemuse the public into believing that new hospitals, new centres, or new doctors were of equal importance to the public health. In a free democracy, for the State to ensure that a citizen had sufficient resources to obtain what he needed was generally to be preferred to actual provision by the State.

The medical profession could serve the community only in proportion to the medical knowledge available. The facilities and resources for research should be greatly increased. Medical education was the channel by which modern research could find expression in the daily work of doctors. The facilities for post-graduate medical education needed to be made more extensive and more accessible to practitioners.

Again, the medical profession had for years maintained that where economic barriers stood between the citizen and existing medical services they should be removed. That issue was not discovered by Sir William Beveridge, for it had been urged by the profession itself over many years. But whether that meant, or should in the public interest mean, that the State should

make provision for those who did not need its help was a different matter. In Lord Acton's dictum, "All power corrupts, and absolute power corrupts absolutely." In a democratic community the State should confine itself to what was necessary in the public interest and not indulge in extensions and controls for their own sake.

The Salaried Service Question

On the subject of the invasion of the personal freedom of both citizen and doctor Dr. Hill said that the function of the State might be taken as the organization and provision of medical services. But this did not involve the assumption of control over doctors rendering individual or personal health service. Provision where necessary should be the keynote of the State's activity. It was not in the public interest that the State should convert the medical profession into a salaried branch of central or local government. This did not mean that salaried medical service was inappropriate to many branches of medical work. The unwillingness of general practitioners for a transition to whole-time status did not mean or imply reflection on that efficient body of men and women in the Public Health Service. The salaried method was clearly appropriate to many branches of work, and to environmental work in particular. The Public Health Service had every reason to be proud of its contribution to human welfare in the last hundred years. But, Dr. Hill suggested, it did not follow that a method applicable to administrative, environmental, and some special clinical services was necessarily the method for personal health services.

Free choice of doctor should be preserved as a basic principle of future health services; and, what was even more important, no administrative structure should be approved which did not both permit and encourage such free choice. Free choice would fade in the whole-time salaried scheme. Whatever fields the State might invade in the public interest, it should leave the doctor-patient relationship untouched. The loyalty and obligation of an individual doctor rendering personal health service to an individual patient should be to that patient and none other. There were many who believed that the ideal doctor-patient relationship based on free choice could flourish only where it was reinforced by a system of remuneration of the doctor based on the number of persons he had at risk or upon the number of items of service he rendered.

Private Practice

There would be those members of the community who, whatever the form of the future medical service, would insist on making their own arrangements. It was not for the medical profession to analyse the motives behind this attitude. There were those who seemed to believe that something you paid for direct was more valuable than something you paid for through taxation or through insurance. This belief was not confined to the wealthier classes. Freedom might be untidy.

If freedom there should be. Those who desired to make their arrangements should have available to them a range of and of doctors no less complete than that which would be available to patients under the official service. In short, who stood outside should be free to make their own arrangements on a fee-paying basis with the doctors of their choice, whether they were doctors in the service or not. The application of this principle would no doubt lead to difficulty. It might well lead to the conclusion that what was necessary to satisfy public health needs was an extension of National Health Insurance to the dependants of existing insured persons and others of like economic status and no more. Others, with their eye on Assumption B, would suggest that the 10% in the upper income group might be permitted, if they so chose, to become voluntary contributors. In any case, there should be freedom for the public to obtain medical services directly, and the doctor should be able clearly to distinguish between those who wished to avail themselves of the State service and those who did not.

Lastly, administrative structure was fundamental. The profession believed that at the centre, whether in the form of a department or a corporate body, there should be an organization concerned solely with health and administration of all the health functions of central government. Associated with it on a statutory basis there should be a medical body to advise on medical issues. As at the centre, so at the periphery: a local adminis-

trative body working over a sufficiently large area and representative of local authorities, the medical profession, and voluntary hospitals. The time had come for a statement of fundamental issues, and the British Medical Association, fully conscious of its duties and responsibilities in representing the profession, was about to place those issues before it. Whatever differences might emerge during detailed discussion the profession should now stand together on fundamentals.

Reports of Societies

STATE NURSERIES

At a recent meeting of the London Association of the Medical Women's Federation, with Dr. ANNIS GILLIE, the president, in the chair, Dr. G. J. BRODIE (Ministry of Health) opened a discussion on State nurseries. The day nurseries, residential nurseries, and nursery classes now available, she said, provided places for 3.2% of the children under 5 in the country. Premises had been chosen with an eye to convenience and pleasantness where possible, but it had often been necessary to use prefabricated huts. Physical health had been the first consideration and mental health the second. The Ministry of Food had co-operated by giving the nurseries special priorities in food. Mrs. ENTHOVEN said that the National Society for Children's Nurseries offered training courses for girls wishing to become nursery nurses, and 40% of girls leaving school wanted to work with children. County schemes of training were now in operation, and the Royal College of Nursing and the Association of Sick Children's Hospital Nurses had collaborated with the society in arranging courses for State-registered nurses who were eligible to take posts as matrons of nurseries.

Dr. MARJORIE BACK pointed out that the day nursery did not solve the problem of the women doing full-time work: the homes of such workers lapsed into squalor. After the war medical women should insist that the married woman with young children was not a suitable person to undertake full-time work. The proper place for the baby under 2 was at home, if the home was a good one. Nurseries for those aged 2 to 5 might perhaps be developed in connexion with community centres with clubs for mothers, like the Peckham Health Centre, and not as part of our educational system. Nursery-minded staff were important for the 2-5 age group, who did not need a State-registered nurse in charge of them, though the health visitor should be in daily contact with the nursery. A child from an inefficient home usually improved on entering a nursery, but a child from a good home often received a check, became fretful, and lost a little weight. The incidence of infections was high in nurseries. Thus in 166 nursery months in nurseries under her care there had been 1,678 days of quarantine—i.e., all fresh admissions had had to be stopped during a third of the time the nurseries had been open. Illnesses had included nearly all the common infections of childhood except diphtheria, against which nearly all had been immunized.

In opening the general discussion Dr. KATHERINE HIRST agreed that the child under 2 was not a candidate for any institution, for both psychological and physical reasons. Dr. HELEN MACKEY said she had been conducting an investigation which kept her for long hours in day nurseries, and she had concluded that in spite of much good will and kindness in the staffs there was apt to be a good deal of shouting from tired women and crying from fretful children, and that there was a high incidence of infection and a low incidence of happiness. Many children minded grievously the separation from their mothers; many were bored with the long hours in which they did nothing. These things might not be obvious in a short visit, but during the last three hours of the day most of the children were crying. They were separated from their mothers from 6.30 in the morning to 6.30 or 7 at night, and it was too long. The infection rate was higher than among children living at home. Of 120 children in two nurseries over a period of six months every child had been absent on the average 1 day in 4. Nearly all those under 2 had running noses and enlarged tonsillar glands. She doubted whether nurseries fulfilled the function for which they were intended.

to make woman-power available. They were expensively armed and equipped, breakages were high, and staffs had to be large. Yet the mothers whom they were supposed to ease often had to stay away from work because the children were ill. She felt that the ill effects on children were not realized by the public, and that the nurseries were squandering rather than conserving woman-power. Other speakers agreed: the communal nursery was not the place for the child under 2; and some thought these young children were better in their own homes, even when these were bad, for there the health visitor could advise and ameliorate.

Correspondence

Lung Complications after Operation

SIR.—The article in the *Journal* of June 19 (p. 754) on post-operative respiratory complications in Service cases by Bird, Lerner, and Martin draws attention to the high proportion of cases developing fever and cough with abnormal signs at the site of one or both lungs following operations for hernial repair—61 in 192 operations. In the same table 26 cases are given following 98 appendicectomies. Reporting on civilian patients, Brock,¹ Sircar and Boston,² and others³ have pointed out that while abdominal operations are responsible for the great majority of chest complications the risk is greater the nearer the operation area is to the diaphragm. Experience in our hospital—26 cases following 170 inguinal herniorrhaphies and in other Service hospitals has shown that this operation does carry a peculiar liability to chest complications.

In this recent report only 3 cases of consolidation were noted, whereas we have found some degree of lung collapse, always the base, in most of those cases showing a rise of temperature to 101°–102° F. This rise occurs typically in the afternoon the day following operation. There is a corresponding rise in pulse rate but not a markedly increased respiratory rate. There is some dyspnoea, but cyanosis is exceptional. Clinically, an impaired percussion note is the one constant sign, and auscultation is not very helpful. Some displacement of the heart beat will usually be discovered, especially if the collapse is on the right side. X-ray films taken within a few hours of onset are not always diagnostic. There may be some shifting of the heart shadow or some elevation of the dome of the diaphragm, but loss of translucency is not often evident for hours or more after onset. The temperature and pulse rate fall to normal within 3 or 4 days, although the atelectatic portion of the lung may not re-expand for many days afterwards.

Decreased movement of the diaphragm is an important factor in the development of post-operative chest complications, and a possible explanation of high incidence following inguinal herniorrhaphies lies in the operation itself. Most surgeons divide the conjoined tendon down to Poupart's ligament. This implies a certain amount of tension, more in the muscular individual, and rather more than drawing together the muscles after a muscle-splitting incision for appendicectomy. The oblique and transversalis muscles are antagonistic to the diaphragm owing to their common attachment to the lower ribs. To limit pain, therefore, diaphragmatic movement will be minimal. The diaphragm is responsible almost entirely for the ventilation of the lower lobes (Hoover), so that deficient ventilation as well as their dependent position render those portions of the lower lobe adjacent to the diaphragm more liable to atelectasis.

I do not think it possible to avoid all chest complications, but we have succeeded in lowering the incidence by routine prophylactic measures which require the co-operation of the nursing staff. Patients are discouraged from slumping into one position in the bed and are encouraged to move from side to side. Deep-breathing exercises are carried out every 2 hours for 24 hours before and 48 hours after operation. Morphine is not given post-operatively unless really necessary.

¹ *Guy's Hosp. Rep.*, 1936.

² *British Medical Journal*, 1940, 7, 82.

³ "Respiratory Excursions of the Thorax," *Oxford System of Medicine*, 1937, vol. 2, Part 1, p. 29.

As shown in this recent report there is a tendency to a high incidence during the summer months, and this may be due to dehydration, the sputum becoming more inspissated and less easily evacuated. Thick viscid mucus is more likely to give rise to the blockage of a bronchus, which is generally considered to be the direct cause of post-operative atelectasis. For this reason we have discontinued pre-operative atropine or scopolamine during the summer months, and anaesthetize hernia patients with a medium dose of pentothal, 0.5 g., followed by cyclopropane.—I am, etc.,

T. F. MILES,
Surgeon Lieutenant-Commander, R.N.

Shortened Puerperium

SIR.—I have been incited by Dr. Hope Simpson's letter (July 3, p. 20), in which he stated that most of the previous letters had been written by those without actual experience of a shortened puerperium, to record the experiences of myself and my father, the late Dr. W. F. N. Haultain, on this subject, as it would seem probable that between us more cases have been treated by a shortened puerperium than by any other observers, at any rate in this country.

My father read a paper on "A Plea for a Rational Puerperium" before the Edinburgh Obstetrical Society in July, 1909, in which he strongly advocated early rising in normal cases, and gave statistics of 100 cases. From that date, until he died twelve years later, he carried out such treatment in all his normal cases, both in hospital and in private practice, and always asserted that in his opinion nothing but good had eventuated. I myself have practised this treatment both in hospital and private practice since 1922 and can fully confirm his views.

So far as I am concerned, however, I let my patients up on the 4th or 5th night and not on the 3rd day as my father used to do, because I like to see lactation well established before allowing them to rise, as there may be some deficiency of milk if the patient is allowed up before establishment has been effected. I would therefore suggest, as is fully stated in my *Handbook*, that early rising: (1) secures better drainage and involution; (2) helps to prevent backward displacement of the uterus; (3) promotes the circulation in the lower limbs and pelvis and prevents any tendency to embolus or phlegmasia; (4) increases muscular tone, thus preventing prolapse and helping the figure; and (5) mitigates constipation.

It is most unfortunate that hospital patients at the present time, owing to lack of accommodation, have to be discharged as early as the tenth day of the puerperium, and it is to be hoped that in the medical Utopia that is promised for the future such patients will be sent to convalescent homes for mothers and babies for at least ten days after discharge from hospital. As it is at present I feel it is better that the hospital patient should be discharged home (where, in many cases, she has to do her household duties again) after she has been up and about for five days and has regained a considerable amount of her strength—if indeed she has lost much after five days in bed—than that she should be allowed up on the 8th or 9th day and be sent home in a much less fit state to be able to cope with her household duties.—I am, etc.,

Edinburgh.

W. F. THEODORE HALTAIN.

Louse-borne Typhus Fever

SIR.—In Megaw's paper (Oct. 3, 1942, p. 401) on typhus fever the opening paragraph says that "zootic" typhus fevers are of minor importance as war diseases, and that these fevers cannot give rise to epidemics such as readily occur in louse-borne typhus. Attention is drawn to a small epidemic in Palestine in 1936, details of which were published in *Trans. Roy. Soc. Trop. Med. Hyg.* and extracted later in *Trop. Dis. Bull.* of 1937, 34, No. 6, p. 476. This epidemic was proved to be a flea-borne one and lice were not found. In view of this Megaw's statement may require revision.

Contact between the soldiers and the collective farms of Palestine, in one of which the above epidemic occurred, is fairly close nowadays. Palestinian soldiers go to these farms on leave, while other soldiers visit them often. A small degree of danger may lurk here. In the second part of the same paper (Oct. 10, p. 433) under "The Other Fevers of the Typhus Group" Megaw discusses the possibility of the virus of flea-

borne typhus, after being transmitted in the first instance from rat to man by the rat flea, becoming at times capable of being transmitted from man to man by human lice, and adds that if this be occasionally possible "the resultant disease would automatically become louse-borne typhus and would have to be handled accordingly." This is a logical view, but in the epidemic mentioned above lice were absent, and, therefore, the possibility of a similar flea-borne epidemic occurring again cannot be overlooked.—I am, etc.,

Symptomatology of Malaria

SIR.—With reference to the most interesting article by Capt. P. H. Birks (June 26, p. 784) someone has described malaria as a "protean" disease. This was very fully proved to those of us who had charge of malaria wards in the base hospitals of Salonika from 1916 onwards. So diverse were the symptoms produced by malignant tertian malaria that in the 43rd General Hospital a classification was drawn up, based on actual cases, showing how malaria may simulate many diseases or even surgical conditions. The classification was as follows:

1. CEREBRAL TYPES OF MALARIA

Diagnosis made in the Field	Type of Malaria
1. Sunstroke, heat-stroke.	Comatose type of malaria.
2. Shell-shock.	Comatose type of malaria.
3. Mental deficiency.	Maniacal type.
4. Epilepsy.	Epileptiform type.
5. Cerebrospinal fever.	Cerebral type.

2. ABDOMINAL TYPES

1. Dysentery.	Dysenteric type of malaria.
2. Cholera.	Choleric type with collapse.
3. Intestinal obstruction, and acute appendix.	Symptoms produced by plugging of capillaries by malaria parasites.

3. PULMONARY TYPES

Bronchitis, pneumonia.	Malarial pyrexia with pulmonary congestion.
------------------------	---

4. CARDIAC TYPES

D.A.H.	Cardiac distress due to haemolysis.
--------	-------------------------------------

5. INFLUENZAL TYPES

influenza, rheumatism.	Pyrexia with joint pains.
------------------------	---------------------------

6. ENTERIC TYPES

interic fever, sandfly fever, trench fever, relapsing fever.	Typhoid-like temperature, and spleno-megaly.
--	--

7. ICTERIC TYPES

jaundice.	Bilious remittent type of malaria. Coffee-ground vomit, icterus, remittent fever.
-----------	---

8. NEPHRITIC TYPES

nephritis	Nephritic type of malaria with albuminuria, haematuria, and pus cells in urine.
-----------	---

9. ANAEMIC TYPES

Pernicious anaemia, debility, phthisis.	Enlarged spleen and profound anaemia due to destruction by parasites.
---	---

All the diagnoses on the left-hand side were taken from the actual field card and are those with which the patient was limited to hospital. All the cases above were confirmed to be either malignant malaria or benign tertian. We found the above—perhaps rather rough—list very useful in putting newly arrived medical officers on their guard against the many diseases which malaria adopts.—I am, etc.,

D. M. M. FRASER.

Treatment of Blackwater Fever

SIR.—Having just read the interesting article on blackwater fever by Lieut.-Col. Felix Smith and Capt. R. Winston Evans (March 6, p. 279) I feel the following case may be of interest.

On Nov. 20, 1942, a Greek, aged about 35, was admitted to hospital from the bush with blackwater fever, which, he said, started 3 days previously. He had a large, very tender liver and his spleen was also enlarged. He was vomiting frequently and his condition was very poor. He was given an injection of 0.3 g. of atabrin immediately. The following day he still had fever and blackwater. Subsequent parasites were found in his blood and another injection of atabrin was given. On Nov. 22, when parasites were again found in the blackwater and fever were the same, it was decided to give him quinine 5 gr. by intramuscular injection: by evening the urine had cleared. On the morning of Nov. 23 blackwater returned and other injection of quinine was given. By the evening the urine was clear and it remained so thereafter. On Nov. 24 and 25 he had daily injections of quinine 5 gr. On Nov. 28 and 29 parasites were again found in his blood and he was given another injection of quinine. Thereafter quinine was administered in small increasing doses by the mouth.

The red cell count on Nov. 24 was 1,200,000; on Nov. 27, 180,000; on Dec. 2, 2,300,000; and on Dec. 9, 3,780,000. He was

given fluids *ad lib.* in the form of barley-water and glucose sodium bicarbonate. On Nov. 23 30 gr. of ferri et ammon. was started four-hourly. He was discharged from hospital on Dec. 1 and returned to his work.

We have felt for some time that blackwater fever cases are overtreated. This is partly due to the long reports which often have to be made on these cases, so that one feels that everything possible should be done. I know this was so up till 1930. These cases usually recover if given ample fluids and efficiently nursed, but malarial parasites must be eliminated. I have found that alkalis, if pushed, are inclined to start vomiting, and the patients then do well if given plain water. Anuria is the greatest danger, and I consider this the only indication for intravenous therapy, except for very severe cases of anaemia. The patients in the three fatal cases I have seen have died after several days of anuria. During the last ten years I have treated twenty-seven cases of varying severity, and have been fortunate enough to have no fatalities. I am, etc.,

City Hospital, Kano, Nigeria.

R. N. HALL.

Clinical Diagnosis of Breast Tumours

SIR.—Valuable information is obtained by placing the patient in the knee-elbow position and inspecting the breasts from the front and sides. Displacement of the nipple or indrawing of the breast in the area of the tumour often becomes apparent in this posture. I have been advised to describe this sign to several surgeons to whom it has been demonstrated.—I am, etc.,

Bournemouth. A. BASIL ROOKE, F.R.C.S.

Cancer of the Lung: A Clinical Sign

SIR.—Cancer of the lung seems to be becoming more frequent. I have been greatly helped in the diagnosis by hearing the lung sounds conducted to abnormal parts of the chest by the tumour. The heart sounds seem to be conveyed when the tumour is in contact with the heart, especially in growths starting in the mediastinum, and they are not heard when the growth begins in the upper lobe or in the outer part of the lower lobe.

In one case, referred to me as a chronic bronchopneumonia, to a persistent cough with occasional rises of temperature to 100° F. the lower two-thirds of the left back were dull and breath sound very weak. In the upper part of this area between the fourth and eighth ribs there was a patch about the size of the palm of a hand where heart sounds were quite loud, but breath sounds and vocal resonance were absent. This led me to diagnose cancer of the lung, which proved correct.

In another patient weighing 16 st., with slight haemoptysis, the hearing of heart sounds in the right third space for two inches from the sternum, where there were dullness, much diminished heart sounds, and no vocal resonance, enabled me to make the diagnosis of malignant disease.

In large tumours on the right side heart sounds can be loudly heard even as far as the anterior axillary line, breath sounds and vocal resonance being absent.—I am, etc.,

WALTER BROADBENT, M.D. Cantab., F.R.C.P.

Consulting Physician to the Royal Sussex County Hospital, Brighton

Nasal Intubation

SIR.—My article (June 5, p. 693) in no way suggested condemnation of nasal intubation in anaesthesia; it only advocated the observance of certain precautions in procedure and the realization of some contraindications, the neglect of which might bring an otherwise excellent method into disrepute because of its ill-advised application.

I agree with Dr. Clendon that complications are uncommon and only infrequently of a severe character, but many of the milder variety never come to the notice of the anaesthetist and only confront the rhinologist later on. When there is any antagonism to nasal intubation it usually comes from the rhinologist, not from any motives of jealousy, as is suggested, but because the rhinologist, from his knowledge and training in intranasal conditions, is the one best qualified to speak of the implications involved. Moreover, he is the one who usually has to deal with any sequelae; consequently his view should receive its just valuation.

Dr. Clendon's assertion that the experienced anaesthetist is able to diagnose "the nature of any obstruction" by passing a tube blindly into the nose and exploring with it is indeed an astounding one. Moreover, his analogy that "the type"

urethral obstruction" can be diagnosed by the passage of a sound or catheter in on insecure foundations; surely inspection through a urethroscope or cystoscope is necessary in most cases before any tentative diagnosis made by such means can be confirmed. Similarly, inspection of the nose by a head-light can alone reveal purulent secretions, soft polypi, or the very large casts of the nasal passage associated with atrophic rhinitis, all of which may be detached by gentle pressure, and propelled onwards towards the larynx as the tube passes down. —I am, etc.,

London, W.1.

A. R. DINGLEY.

Oedema of Extremities at Sea

SIR.—Dr. H. E. Thorn (June 5, p. 708) remarks on the occurrence of oedema of the feet and ankles in fit men during a voyage. I believe this is not an uncommon condition when on passage from temperate climates to the Tropics, and under these conditions I have observed eight or nine cases in a destroyer. I believe the cause of the condition is the heat of the sun and of the decks damaging the capillaries of the feet and ankles, which, because of their anatomical position, bear the greatest weight of blood. In my cases it was impossible to relieve the men of their duties, and *lotio plumbi* only was used, the condition clearing up in about a week. In two cases calcium lactate was given with no benefit. The rational treatment for men in a troopship would seem to be to relieve the damaged capillaries by keeping the feet up.—I am, etc.,

T. E. BARWELL,
Surgeon Lieutenant, R.N.V.R.

"Better Sight without Glasses"

SIR.—Bates's theory cannot be entirely dismissed. Orthodox orthoptic training has shown that relaxation exercises can be most efficacious when the muscles of the eyes need relaxation. Cases of low hypermetropia, where symptoms of asthenopia are present, are usually corrected with plus lenses, while deeper investigation would in all probability reveal convergence insufficiency of an exhaustion type. Orthoptic training has shown us that what is more effective than plus lenses, in many of these cases, is treatment by means of relaxation exercises, resulting in the elimination of the cause of the insufficiency, whereby the patient can overcome the small amount of hypermetropia without the aid of glasses. Apparent and *pseudo-myopia* are treated by means of orthoptic training in exactly the same manner, the spasm of accommodation being unlocked by relaxation. Bates's methods have by coincidence cured these types of cases, but his physiological basis is entirely incorrect, and to generalize, as he does, is positively harmful and gives false hope to many.

I have seen a few of Bates's "cures" and had the opportunity of examining these cases. They were invariably cases of *pseudo-myopia*, and each one had, in the first place, unfortunately obtained normal visual acuity by wearing very weak minus lenses. Bates's relaxation exercises (corresponding to orthoptic training exercises on the synoptoscope type of instrument) had unlocked the spasm of accommodational-convergence and the patient had "thrown away his glasses." —I am, etc.,

London, W.1.

MARGARET DOBSON.

Pediculus pubis in the Eyelashes

SIR.—In recent months I have seen at the Prince of Wales's General Hospital two cases of *Pediculus pubis* lodging in the eyelashes: this particular location, though recognized, must be exceedingly rare.

The first case was that of a young man; he observed something moving in his eyelashes, tried to catch it and failed: he said that it disappeared under his upper lid. He went to his doctor, told him about it, and the doctor, seeing nothing, told him he was imagining things. Fired by this taunt, he watched, waited, and caught it, and brought it in triumph to the hospital, where the pathologist, Mr. Benians, readily identified the parasite. I referred the patient to Dr. Klaber, who reported that he was a hairy man and the infestation widespread; of this the patient seemed to be unaware. The second case was that of a girl of twenty. The history is similar. She also had observed it and informed her doctor, who was equally unbelieving. She then organized a search of her eyelashes, and with the help of a friend caught one—and lost it. This

patient was brought to me by Dr. Klaber, who had found a heavy infestation in the left axilla and a lighter one in the right.

It seems probable that the parasites were carried to the eyelashes on a finger. In view of the tendency of this parasite to avoid the light, it seems unlikely that it would multiply in the eyelashes, and even its survival is not likely to be of long duration.—I am, etc.,

London, W.1.

NORMAN FLEMING.

Bran in the Diet

SIR.—There are, I am convinced, some individuals whose bowels act more satisfactorily and who feel better if to their daily food they add bran, the exact quantity differing in different persons and varying from time to time, partly in relation to the kind of food in the diet. By this simple means such individuals are generally able to avoid all other treatment for constipation. The bran seems to act by increasing the bulk of the unabsorbed contents of the large intestine rather than by its particles irritating the mucosa. Specially prepared bran (such as "All-bran") is certainly very convenient to use, but owing, I suppose, to its having been classified among "luxury" cereal instead of among "medicinal" preparations it is not now sold in London and the southern zone of England, though it is still obtainable in Liverpool and the North. Those who require it in London can, therefore, only obtain it in some way from the northern zone—for instance, from Liverpool.

They can, of course, use ordinary bran instead. Unfortunately the latter cannot be bought from bakers or ordinary provision shops, but only from millers and with the help of a special permit. By eating bran-containing bread the requisite amount of bran may doubtless be consumed, if one does not mind habitually and wastefully overloading the digestive system with superfluous—and therefore probably harmful—food which has to be swallowed in order to obtain the requisite amount of bran. The stringy cellulose of cabbage does not do equally well in many cases. I hope this at first sight insignificant question may attract the notice of doctors who are consulted by the Ministry of Food.—I am, etc.,

London, W.1.

F. PARKES WEBER.

Water for Rabbits and Guinea-pigs

SIR.—Dr. T. Hare (July 3, p. 24) says: "If Dr. E. L. Kennaway had been familiar with the literature of rabbit and guinea-pig management, a good selection of which was bequeathed by the late Henry Gray to the library of the Royal College of Veterinary Surgeons, I think he might have modified some of his statements." Perhaps Dr. Hare would point out the statements in my article which require modification. I confess at once that I was ignorant of the writings of the rabbit fanciers of the last century, and of the bequest of this literature by Dr. Henry Gray, and can only express regret that I did not refer to these authorities. But whatever may be the knowledge on this subject which is laid up in libraries, in the world outside there is widespread ignorance on this question. From the humanitarian standpoint this matter is urgent; the exact attribution of credit to earlier generations of rabbit keepers is in comparison unimportant.

We must be grateful to Dr. Hare for bringing to light the old rule that rabbits on dry food "require about one-third of a pint of milk or water daily." One-third of a pint is 190 c.cm. This provides a rather wider margin, for the largest animals, than the 160–170 c.cm. which we found to be drunk by rabbits of medium size. Dr. Hare tells us also that "the old fanciers recommended about a tablespoonful of water or milk daily" for guinea-pigs on a dry diet. This is certainly a cautious rule; some of our guinea-pigs here drink much larger amounts. Hale-White,¹ in defining a tablespoonful, says, "usually it is very nearly 15 c.cm." but some spoons of this category hold over 21 c.cm. An adult guinea-pig of 600–700 g. is about 1/4 the weight of a rabbit and might be expected to require 1/4 as much water. On the "one-third of a pint" rule for rabbits a guinea-pig should receive $\frac{190}{4} = 48$ c.cm. The older literature to which Dr. Hare refers would no doubt give the grounds upon which the "tablespoonful" rule is based.—I am, etc.,

A Non-electric Suction Apparatus

SIR.—Dr. N. F. Saher and Mr. R. Salt are to be congratulated on their article (June 26, p. 790) where they describe improvements in the application of the injector. Our improvements in this application of the injector (*Lancet*, June 12, 1943, p. 738) have gone even further. These are: (1) we have eliminated the "foot-hand complex" by replacing the foot control with a simple valve on the actual sucking inlet; (2) the time lag to develop high negative pressures is abolished by having available constant negative pressure without the injector working continuously. This is achieved by an automatic device regulating the positive pressure side of the injector. This device is a simple diaphragm, controlled by an inlet from the negative-pressure side, and it can be adjusted to operate through any range of negative pressure; (3) there is no limit to the capacity of the receiving bottle or bottles with our apparatus, as negative pressure is maintained all the while and does not have to develop each time the suction tips or catheters are used.—I am, etc.,

Twickenham.

NORMAN R. JAMES.

Specialists and State Service

SIR.—There are only a few points in Dr. S. Cochrane Shanks's letter (June 26, p. 802) that call for comment.

My original questionnaire was sent to the membership of the British Institute of Radiology, and only the replies from the medical members were considered for the published figures. The survey was, therefore, representative of radiologists throughout the country and not confined to a small group of "consultants." The Faculty of Radiologists is really a branch of the British Institute of Radiology and has a membership of a limited character, but practically all members of the Faculty are also members. My figures were compiled from a representative circularization of the country as recently as three weeks before publication of my letter (June 5), but is it not the case that the questionnaire sent out by the Faculty was circularized as long as two years ago? I make this observation subject to correction, but if my information is correct, surely the dangers of advising to-day on the return of a two-year-old plebiscite must be obvious, and I think this is the real answer and not that suggested by Dr. Shanks. May I suggest the Faculty organize a new questionnaire and vote and think again after this referendum. This observation also answers the second paragraph of Dr. Shanks's letter, and may further raise the question as to whether or not the B.M.A. has got a really correct impression to-day of the desires of radiologists from a questionnaire two years old?

My information about the activities of the Faculty is quite up to date irrespective of the fact I did resign my membership of that body in 1940, on the grounds of disagreement with its inadequate policy towards members and the national effort.

It is interesting to learn the Faculty do not favour full-time State medicine; but, after reading the pamphlets issued by the body, it is still difficult to discover where it rejects full-time State salaried service. It would be of great assistance to hear briefly and concisely the details of the actual form of organization for radiologists the Faculty does favour.—I am, etc.,

London, W.1.

NORMAN P. HENDERSON.

Specialist Courses for Service M.O.s

SIR.—Mr. Bevin's plan for training persons discharged from the Services having brought this problem into public consciousness one may be permitted to consider for a space the position of the younger members of our profession who at the outbreak of war had been qualified three years or thereabouts and were holding posts of the registrar type with the object of obtaining a higher qualification. Many of these young doctors joined up at, or soon after, the outbreak of war, and so lost the opportunity of working for the qualifications they desired. I think any medical man will agree that work done under Service conditions is not likely to produce success in examinations of a clinical nature. The atmosphere is difficult for the student, there are disturbances and interruptions beyond his control, and the nature of Service duties is not of great value for clinical work except for a fortunate few, and even the Service hospital cannot, by its nature, provide the necessary facilities

for the clinical study and work required, however hard student may apply himself to his reading in off-duty or slack times.

Can our teaching institutions give a thought to the salvation of this group, now into the early 30's, many in the narrow course of events married, but still hoping to be able to pick up the threads of their interrupted careers when eventually demobilized or otherwise discharged, but not wishing to return to general practice or public health work? I feel certain this question will interest many members of the 28-33 group, and a suitable scheme would result in many being sent for the clinical specialties and future hospital staffs who would otherwise be forced to take up general practice—when, do less, they would do a good job of work, but not so good as they could do—or go into public health, a branch of the profession which they would probably dislike and for which they show little aptitude.

No person can do good work if he dislikes it and feels he could do something else much better—a fact recognized by the industry by the efforts of the psychiatrists, but which seems in danger of being forgotten as applied to the various branches of our own profession. No one can deny that the surgeon, the physician, the medical administrator, and the hygienist have different types of minds, and that vocation must play a large part in selection. If the system of automatic direction of people into posts should persist in civil life, the resulting work will be mediocre even though it may be competent.

Vague and nebulous promises of "if you do your bit you won't be forgotten" cannot help the budding surgeon who has not handled a scalpel for four years to remove his appendix, nor can they—quite rightly, when dealing in civil life as we do—impress an examiner or a hospital board with a choice for an R.S.O. or R.M.O. between one who has last surgery or clinical medicine was four or five years ago, and one who has been doing such work all along by some fortunate chance. Others of your correspondents may have some views on this matter.—I am, etc.,

L. W. ALDRIDGE.

Doctors and the Future

SIR.—I would offer the following points as a brief answer to Dr. C. A. H. Franklyn's question in his letter (June 26, p. 801) asking what is considered wrong now: (1) The gravitation of doctors towards the better paying areas often away from the more densely populated districts. (2) The buying and selling of the goodwill of practices. Financial rather than medical ability determines the size of a practice. The cost of treatment is inflated by the interest paid to the moneylender. (3) Many practices are too large for the number of doctors engaged in them to give due attention to all their patients. (4) Practices are frequently ill equipped in buildings, furniture and professional appliances. The doctor does not find that the fees he can earn justify the outlay necessary for proper equipment. (5) A feeling prevalent among the poorer sections of the public that it is not getting the best possible medical service. (6) Lack of sufficient hospital accommodation, shown by long waiting lists. (7) The artificial cleavage and, at times, antagonism between curative and preventive medicine.—I am, etc.,

Bristol.

N. S. B. VINTER.

The Edinburgh Surgical Fellowship

SIR.—The Royal College of Surgeons of England is celebrating the centenary of the Fellowship on July 21, and I think it may interest the Fellows of the sister College of Edinburgh to know something of their Fellowship. The foundation of the College goes back to 1505, but it was not until 1778 that it was incorporated by Charter granted by George III as the Royal College of Surgeons of the City of Edinburgh, where its members were then called Fellows. In 1851 Queen Victoria granted another Charter and the name and title were changed to the "Royal College of Surgeons of Edinburgh," the word "City" being omitted.

The Fellowship of the College was only obtainable by examination, the production of a thesis, and the entrance to the Widows' Fund of the College. These restrictions, especially the expense incurred—some £300—formed a barrier to many

sirous of this honour. They remained in force until 1884, when the Council decreed that the thesis and entrance to the 'dows' Fund should be eliminated, but an examination of a stricter character should be exacted of all ordinary candidates, who, after passing it, should be balloted for by the Fellows, and this arrangement is being followed at the present day. It is somewhat curious to learn that although there were no ordinary Fellows until 1778 we find that an Honorary Fellowship was conferred on Sir Andrew Ramsay on Oct. 17, 1671, from thence, of course, many up to the present time—am, etc.,

C. W. DEAN, F.R.C.S.E.D.

Obituary

A veteran member of the profession, Dr. EDWARD THOMAS RICHARD, died in retirement at Hove on June 10. He studied medicine at the University and the Royal College of Surgeons in Edinburgh, and graduated M.B., C.M. in 1885, proceeding D. in 1908. Part of his life was spent in China, where he was for 7½ years the post of medical superintendent of the King Hospital and lecturer in the medical department of the Peking College. Dr. Pritchard joined the British Medical Association in 1890 and remained in active membership up to the end of 1936, by which time his sight had failed and he was unable to read.

Dr. F. E. ROWAN-ROBINSON died on June 11, aged 65. He qualified at Edinburgh University as M.B., Ch.B. in 1900, and joined the R.A.M.C. shortly afterwards. He served in the South African War, Aden Hinterland Campaign, and in the war of 1914-18. He was invalided in 1921. He returned to medical work during the present war, being a member of a London consulting board and continuing this work till progressive malignant disease compelled resignation. By his kindness and courtesy Dr. Rowan-Robinson won the affection of a large circle of friends. He leaves a widow but no family.

Dr. MALCOLM McLARTY, who died on June 12 after a short illness, had a distinguished career at Edinburgh University, where in 1895 he graduated M.B., C.M., and in 1898 B.Sc. in Public Health. Thenceforward he carried on an extensive practice in the city. He was one of the senior Fellows of the Royal College of Physicians of Edinburgh, his election dating from 1911. He had been a member of the B.M.A. for 46 years. His patients and friends Dr. McLarty was known as a man of great charm and gentleness and integrity of character, with wide general interests and a cultivated mind.

The Services

Temp. Surg. Lieut. T. M. C. Roberts, R.N.V.R., has been mentioned in dispatches for endurance and good services to the wounded on his ship, H.M.S. *Lightning*, had been sunk.

Major (Temp. Lieut.-Col.) J. S. Richardson, R.A.M.C., has been appointed a Member of the Royal Victorian Order (Fourth Class). The *London Gazette* announces the appointment to M.B.E. (Civil division) of Mrs. Margaret Henderson Thomson, M.B., Ch.B., alaya Medical Service. The announcement reads as follows:

Dr. Thomson was wounded by a bomb splinter just before leaving Singapore, when the Japanese had dive-bombed the evacuation ships, she was picked up by a lifeboat and rendered invaluable aid among the wounded. Noticing that a boat was badly undermanned, she took an axe herself and, despite her own wounds, pulled hard for four hours and did much to encourage and keep up the morale of the boat's company. For three days, while marooned on that island, with no food at all and very little water, she continued to attend wounded women and children. Later, on Senajang island, she took charge of over fifty wounded cases, and tended them day and night, in spite of a serious shortage of medical supplies and with the crudest of surgical appliances. She also assisted greatly in the safe evacuation of the most urgent cases to other island hospitals. But for her resolution and disregard of self many of the people would have died, and it was due to such sacrifice on her part that her wound turned septic and she followed her own patients to hospital, where she displayed admirable courage throughout the difficult journey across the straits.

CASUALTIES IN THE MEDICAL SERVICES

Died on Active Service.—Major J. N. Strauss, R.A.M.C.
Previously Reported Missing, now officially Reported Prisoner of War.—Lieut.-Col. (acting Col.) K. P. Mackenzie, R.A.M.C.
Prisoner of War.—Capt. G. S. Riddell, R.A.M.C.
Previously Reported Missing, now Reported Prisoner of War.—Capt. A. Farquhar, R.A.M.C.
Killed.—Temp. Lieut.-Col. A. Macdonald, R.A.M.C.

Universities and Colleges

UNIVERSITY OF OXFORD

In a Congregation held on July 1 the following medical degrees were conferred:

M.B., B.Ch.—J. A. Ritchie, *R. E. Lee.
* In absentia

UNIVERSITY OF BIRMINGHAM

At a Congregation on July 3 the following degrees were conferred:

M.D.—Prof. A. C. Frazer and Prof. J. M. Webster (ex-officio), I. J. L. Collis.
M.B., Ch.B.—J. E. A. Barker, J. V. S. Brookes, J. A. Kathleen M. Lawrence, J. R. W. Tudor, J. J. N. Wilson, L. E. Arundell, Ursula M. Baines, Helen J. Bayliss, E. R. Bickerstaff, R. L. Bashon, P. Brown, Kathleen M. Chipperfield, G. I. Clarke, M. A. Cooke, F. Cullis, P. Dawson-Edwards, C. B. Eccles-Smith, Jean Edmonds, C. G. Edwards, H. J. H. Evans, K. W. Forber, J. Hallam, A. H. Hamed, J. G. Hoult, A. Jarrett, L. Joseph, Beatrice Kaelin, A. R. Kenderdine, Eileen M. MacShane, Julia M. Neal, Margaret Newton, K. I. Price, Joan Stanton, L. J. Totham, J. Tregillus, L. W. Waters, T. A. White, J. Yvonne J. Williams, Barbara D. Wright.

The following scholarships, medals, and prizes have been awarded:

Queen's Scholarship (third year), K. D. Roberts; (fourth year), J. N. Omond; (fifth year), Theresa Lazar; (final year), V. S. Brookes. *Ingleby Scholarships*, V. S. Brookes, Kathleen M. Lawrence. *Forwell Memorial Medal*, J. N. Wilson. *Garnett Memorial Medal*, R. W. Tudor. *Pringley Smith Prize in Ophthalmology*, V. S. Brookes. *Battersworth Prize*, V. S. Brookes. *Leith-Newman Prizes in Pathology* (fourth year): Medical, J. L. Stafford; Dental, D. H. Goose. *Thompson Prize in Anatomy* (third year), K. D. Roberts. *Russell Memorial Prize*, J. G. Hoult, R. A. F. Jack. *Humphreys Memorial Prize*, E. A. Marsland. *Windle Prize in Anatomy*, G. A. Readitt.

1 First-class honours. 2 Second-class honours. 3 Distinction in medicine. 4 Distinction in midwifery. 5 Distinction in surgery.

UNIVERSITY OF MANCHESTER

The following candidates have been approved at the examinations indicated:

M.D.—By thesis: T. E. Barlow, I. B. Finkleman, I. I. Harvey Flack, I. W. H. Shapley. By examination: G. Bridge.
Final M.B., Ch.B.—J. P. Mackay, J. S. B. Rampling, J. A. F. Robinson, J. R. Tepper, J. S. Battersby, D. C. A. Bevis, D. H. Blakey, H. M. Blaquiere, D. L. Boardman, H. L. Brusk, C. P. Brown, O. O. Cowpe, Frances G. Danson, C. J. Denhurst, P. R. Dutton, B. I. Einhorn, Nora F. M. Falk (Mrs. Wilkinson), F. Fletcher, J. W. Fletcher, J. Margaret Garrett, J. Grayson, G. Harveys, J. C. Howarth, Mary W. P. Huddart, F. Jackson, Marjorie T. Lee, Mary P. McGlade, E. B. N. Marchant, Doreen Mitchell, J. G. Oddy, S. Portnoy, Ruth J. Prausnitz (née Whitley), P. T. Quinlan, P. H. Renton, R. H. Sewell, J. H. Shelswell, K. H. Smith, H. Sosnowick, J. L. Taylor, L. S. L. Turner, P. Vulsions, J. E. G. Wade, Margaret Wardle, T. A. Yates. Part I (*Forensic Medicine and Hygiene and Preventive Medicine*): H. W. Ashworth, W. G. Astley, F. Bailey, D. G. Berry, R. B. Broughton, R. W. Burling, J. H. Dargie, Constance M. Dudge, Doreen M. M. Dutton, G. V. Feldman, I. L. Gregory, Margaret Hedley, J. D. Heppleston, J. Hewer, R. Hierons, Marion E. Jepson, F. Latham, Margaret M. Lawton, Marion D. T. McIntosh, H. McIntyre, H. B. Marsden, T. M. Martin, Joan A. Mettam, B. Nicholson, T. A. Nowell, Nancy B. Penney, L. Rose, P. W. E. Sheldon, J. A. Shrigley, L. Shuck, H. Tabuss, A. E. Thomas, Elizabeth Travers, G. S. Turpin, W. V. Wadsworth, G. H. Watson, B. Wilkins, P. O. Yates, J. Sharp.

1 With commendation. 2 Awarded second-class honours. 3 Distinction in medicine. 4 Distinction in surgery.

UNIVERSITY OF ST. ANDREWS

The following medical degrees were conferred on June 25:

M.D.—G. H. Robertson (with honours for thesis), D. M. McGillivray, M.B., Ch.B.—J. G. Lawson, J. A. L. Webster, J. W. F. Spraggour, J. W. F. Mills, J. D. Stephen, J. W. L. MacD. Perry, J. W. Eadie, J. W. M. Walker, J. A. Hershell, J. Constance F. Drysdale, J. Violet Auld, J. M. Asken, Sheena M. Allardice, G. M. Ashurst, Ann B. Austin, Ann E. Bruce, J. M. Brunton, Mary E. Bryson, W. E. A. Buchanan, W. Christie, Sheila G. F. Conacher, Frances R. T. Broadbent (for Cruickshank), W. Davidson, D. A. E. Dewar, J. G. Fisher, J. L. Fyfe, A. C. Hay, Frances C. Kerr, J. A. R. Lawson, Margaret P. Laxton, Joan I. McCracken, I. C. R. Macdonald, R. A. Murray, B. A. Marshall, Doris C. Morgan, R. M. Manro, Sheila M. Ore, Evelyn J. Rounthwaite, Daphne M. Scott (for Rusforth), S. N. P. Stobie, R. Summers, I. M. C. Troop.

1 With distinction. 2 With commendation.

The following prizes were presented:

Price Memorial Prize (Surgery): L. Fraim-Bell and A. G. Watson. *Capt. W. A. Low Prize and Medal in Medicine for the most distinguished graduate*: J. G. Lawson. *MacEwan Prize (Surgery)*: A. L. Webster. *Robert Davies Roys Prize (Medicine and Pathology)*: J. W. F. Spraggour.

NATIONAL UNIVERSITY OF IRELAND

At the summer examinations held at University College, Cork, the following candidates for higher medical degrees were approved:

M.D.—E. J. Caniffon, T. Creedon, Nora A. Hayes, D. J. O'Callaghan, M.Ch.—M. D. Hickey, R. F. O'Driscoll, M.A.O.—J. B. Kearney.

QUEEN'S UNIVERSITY, BELFAST

The following candidates have been approved at the examination indicated:

M.B., B.Ch., B.A.O.—Una B. Byrne, J. Cully, Ethel A. Fisher, H. N. Glancy, B. Gorkulke, W. J. B. Higson, E. D. Lindsay, C. W. McKee, R. A. McKee, Una McGilgan, R. Millar, W. J. Moffett, Hilda A. Reade, J. C. S. Ritchie, Zdenek Steiner, Kathleen H. Stewart.

UNIVERSITY OF DUBLIN

SCHOOL OF PHYSIC, TRINITY COLLEGE

The following medical degrees were conferred on June 30:

M.D.—D. T. Bardon, M. C. Drough, A. F. J. Delany, M. H. Fridjhon, C. P. Clancy-Gore, S. Seivitt.
M.B., B.Ch., B.A.O.—M. T. S. Conradian, C. S. Cummins, Lorna R. J. d'Abreu, A. P. Dignan, A. J. H. Donnell, Margaret E. Eccles, D. F. S. Flood, E. F. B. Forster, J. M. Garvin, P. G. Harris, R. T. John, P. J. Keane, Mona M. F. Kelly, D. K. Kiersey, T. C. Kirkpatrick, G. M. C. McBrien, T. J. Macdougald, C. R. F. McDowell, J. A. O. Mulcahy, Elizabeth A. Robinson, M. S. C. Rooney, A. O. Sasegbon, E. B. Stephens, T. N. Strong, A. H. E. Thomas, D. D. Towle, T. J. C. Warriner, C. B. Wilson, J. S. Wood.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

New Regulations for the Fellowship

The Council of the College has revised the regulations for the Fellowship, and the Primary Examination beginning on Nov. 29 next will be the last to be conducted under the present regulations.

New regulations approved by the Council will become effective after the end of 1943. These regulations embody the following changes: (1) the Primary Examination cannot be taken by undergraduates, but will be open only to Members of the College, or to graduates in medicine and surgery of the Universities and Medical Colleges recognized by the Council for the purpose, who are able to comply with the conditions; (2) the subject of the Primary Examination will be (a) anatomy (including normal histology), and (b) applied physiology and the principles of pathology. A synopsis indicating the general scope and spirit of the examination in applied physiology and the principles of pathology is published in the new Regulations.

With regard to the Final Examination, no candidate will be admissible without producing evidence of having been engaged in the acquirement of professional knowledge for not less than two years after obtaining the Membership of the College or some other recognized qualification (see 1 above).

The dates of the examination have been rearranged so that it will be possible for candidates who pass the Primary to proceed immediately to the Final Examination, if they are eligible. During 1944 the examinations will begin on the following dates: Primary, April 24 and Oct. 23; Final, May 4 and Nov. 2.

Copies of the new Regulations and full particulars may be obtained post free from the Director of Examinations, Examination Hall, Queen Square, London, W.C.1.

Medical Notes in Parliament

Medical Examination of Home Guard

On June 22 Mr. E. P. SMITH asked the Secretary of State for War if his attention had been called to the coroner's verdict at the inquest on Mr. Arthur Chudney of West Wickham, Kent, to the effect that death was occasioned by heart failure due to and following strain while engaged on military Home Guard duties, and whether, in the light of this fact, he would consider his recent refusal to institute medical examination of the Home Guard. Mr. ARTHUR HENDERSON said he understood that before the exercise it was explained to the men that they should fall out who felt they were not equal to it or found the course of it that the training was too hard. Much as he deplored the death of this Home Guard, he did not consider that the facts of the case showed that the arrangements outlined in the answer given by the Secretary of State for War on June 1 should be modified. Mr. SMITH asked, now that the Home Guard were qualified for military death and disability pensions, what logical alternative there was to giving them proper and periodical medical examinations, together with grading for duties. Mr. HENDERSON said it would be extremely difficult to carry this out, having regard to the number of the Home Guard and the number of doctors available.

The Medical Register

On June 29 Sir E. GRAHAM-LITTLE asked the cost to the Exchequer of the production of the *Medical Register* and the average annual sale of the volume; and whether Sir John Anderson would take steps to improve the preparation of the *Medical Register*, for the printing and publication of which the General Medical Council was responsible. Sir Ernest asserted that its record of addresses and medical qualifications of doctors was less accurate than the *Medical Directory*, which was produced by private enterprise. Sir JOHN ANDERSON replied that the production of the *Medical Register* involved no charge on public funds, its cost being defrayed from the resources of the General Medical Council. The average annual sale in the three years immediately before the war was 785 copies, and in

the years 1940-2 475 copies. The *Register* was not primarily intended to serve the purposes of a directory, but, as was stated in the preamble to the Medical Act, 1858, which provided for the keeping of the *Register*, to enable persons requiring medical aid to distinguish qualified from unqualified practitioners. Owing to pressure on their reduced staff and to the difficulties under war conditions of ascertaining whether the registered addresses of many practitioners in the *Register* remained correct, the G.M.C. had found it impracticable to maintain a normal procedure of periodically verifying addresses by written inquiry. He had no doubt, however, that this procedure would be resumed as soon as normal conditions were restored. Section 30 of the Medical Act, 1858, enabled but did not oblige practitioners to have inserted in the *Register* certain additional qualifications to those by virtue of which they were registered. Legislation would be required to make the *Register* a complete record of additional qualifications of such standing as to deserve recognition in it.

Medical Services and Staffs of Government Departments

Replying to Sir Percy Hurd on June 29, the Financial Secretary to the Treasury stated that the following Departments provided medical services for their staffs, the numbers of medical and associated personnel and the estimated cost being as stated:

Department	Personnel	Cost £
Admiralty	99	43,000
Ministry of Supply	765	210,000
Customs and Excise	2	1,265
Inland Revenue	1	750
Ordnance Survey	4	250
Post Office	25	12,272

In addition; about £65,000 was expended by the Post Office in respect of similar services to some 2,600 local medical advisers.

The following Departments had medical services for the purpose of fulfilling their administrative functions, the numbers of medical and associated personnel and the estimated cost being as stated:

Department	Personnel	Cost £
Broadmoor Criminal Lunatic Asylum	25	10,100
Prison Service, England and Wales	141	56,820
Supreme Court of Judicature	2	3,300
Prison Service, Scotland	14	3,340
Board of Control	427	104,000
Ministry of Pensions	1,276	305,883
Board of Education	8	8,140
Scottish Education Department	1	1,100
Ministry of War Transport	2	1,700
Ministry of Health	162	138,580
Welsh Board of Health	9	10,370
Department of Health for Scotland	39	34,266
Ministry of Labour and National Service	14	14,032
India Office	3	1,750
Colonial Office	2	2,350
Ministry of Fuel and Power	10	9,000

It was not possible to say how these services might be affected by the Beveridge proposals.

Diploma in Public Health

Sir FRANCIS FREMANTLE asked on June 30 if steps were taken to reconsider the courses and examination for the Diploma in Public Health in accordance with modern requirements, for which the present regulations were insufficient out of date. Sir JOHN ANDERSON answered that the present Resolutions and Rules of the General Medical Council Diplomas in Public Health came into force in October, 1938-9 a visitation of examination for such diplomas made by the Council. The general report of the Public Health Committee of the Council on the visitation, which was published in May, 1940, criticized the examinations in detail did not appear to support the suggestion that the Resolutions and Rules were insufficient and out of date. In any case war conditions would make any general revision of the curriculum for such diplomas inopportune.

Tuberculous Infection in Nurses

On July 1 Mr. BROWN told Mr. Messer that there were figures showing the number and percentage of nurses employed in general hospitals who contracted pulmonary tuberculosis. In the report of the M.R.C. Committee on Tuberculosis in Wartime, published in Oct. last, it had been stated that even from other countries and expert opinion in our own suggestion that the risk of contracting tuberculosis from nursing tuberculous patients in sanatoria was no greater than that involved in general hospital nursing. The Registrar-General's supplement of 1931 regarding occupational mortality observed that mortality statistics provided no evidence of special occupational risk of tuberculous infection in the nursing profession.

Soldier's Death in Detention Barracks

On July 6 Sir ARCHIBALD SOUTHBY asked the Secretary of State for War what action was being taken about the military orders who failed to ascertain the true medical condition of late Rifleman Clayton, whose death occurred recently in military detention barracks. Sir JAMES GRIGG, replying to and several other questions, said that the Government had decided that an independent inquiry should be held into conditions at Navy and Army detention barracks generally, and he had shortly to announce who would conduct the inquiry. It would, of course, be for the inquiry itself to determine the manner in which it would conduct its proceedings. In the meantime the Military Court of Inquiry on the special case of late Rifleman Clayton was sitting, and in accordance with the usual practice this inquiry would not be open to the public. Sir RHYD DAVIES asked if inquiry would be made into the responsibility of the doctor who certified Rifleman Clayton as fit for duty. Sir JAMES GRIGG replied that he had had the report of an inquiry into that particular aspect, but he had not time to study it and was not in a position to say anything at present. Sir ARCHIBALD SOUTHBY asked if the Secretary of State would see that the terms of reference of the Court of Inquiry laid particular stress on inquiry into the action of the doctor who failed in his duty and did not see that the man was unfit for duty. Sir JAMES GRIGG said he would give any terms of reference to the court which would seek to prejudice any action in advance. The terms of reference would certainly cover medical arrangements.

Sir A. CUNNINGHAM-REID asked the names of the doctors who had seen the late Rifleman Clayton, who was suffering from eczema, as fit for the Army. Mr. GEORGE TOMLINSON, replying, said that the whole of the circumstances of this case were at present the subject of inquiry by the Secretary of State for War, and the Minister of Labour was not prepared to give partial information in advance of the results of the inquiry with regard to particular aspects of the case. Sir SUMMERSKILL asked if Mr. Tomlinson was aware that many doctors who had read this case had said of themselves: "There, for the grace of God, go I"?

Commissioned Rank for Masseuses

On July 6 Sir FRANCIS FREMANTLE asked the Secretary of State for War why the same prospect of advance to commissioned rank given to nurses and to physiotherapists in overseas theatres was refused to women specially trained as masseuses, and to other physiotherapists; and whether he would receive deputation from the Chartered Society on the subject. Mr. ARTHUR HENDERSON replied that masseuses were employed in the War Department as civilians under conditions of employment accepted by the Chartered Society of Massage and Medical Gymnastics. This arrangement was working satisfactorily, and he was not satisfied that the adoption of Sir Francis Fremantle's suggestion would improve the present service of masseuses. He would gladly see a deputation on the subject. Sir FRANCIS FREMANTLE asked if it was not true that the Chartered Society entirely disagreed with that statement. Mr. HENDERSON replied that the Chartered Society were very anxious to have commissioned rank, which was the same thing as being employed as civilians from outside the Army. Mr. HENDERSON said that the deputation would be an opportunity of conveying those views.

Appeal Tribunals: Bill Held Over

When the House of Commons went into Committee on the Pensions Appeal Tribunals Bill, on July 1, Mr. QUINN HOGG moved the first of a series of amendments designed among other things to remove from the Bill the provisions limiting the appeal concerning grants. After vigorous debate Mr. EDEN emerged as Leader of the House to move to report progress and suspend consideration of the Bill. He said it was natural that the House should prefer to look at the matter again when it knew what proposals the Government was going to bring forward affecting the Royal Warrant on pensions. He was willing that the Bill should stand over till the Government's final proposals were made available to the House. Sir WALTER WOMERSLEY said that anything contained in an amended Royal Warrant would be binding on the tribunals. Progress was then reported.

Medical Board Rejections

On July 6 Mr. HEWLETT asked the Minister of Labour if he could ensure that when doctors discovered on medical examination any latent disease of which a called-up man might be aware he was in all cases told the exact reason for his rejection so that he might take private advice. Mr. TOMLINSON replied that it was formerly the practice to do this, but the results were found to be unsatisfactory for various reasons. It was now the practice in such cases for the Medical Board to advise the man to consult his own doctor.

Propaganda, Bad and Good.—On June 24 Viscount HITCHING-BROOKE asked whether Mr. Brown knew that the National Anti-Vaccination League circulated literature to expectant and nursing mothers advocating a course of action with regard to vaccination and diphtheria immunization contrary to the declared policy of his Department. Mr. BROWN said he knew of this and was of opinion that it was best countered by effective and positive action. The Ministry and local authorities were therefore continuing propaganda to advise parents to have their children protected by methods supported by the best medical opinion.

Certification Panel at Burnley.—Answering Mr. Burke on June 10, Mr. BEVIN said that on their own initiative medical practitioners of Burnley had formed a panel, meeting once a week at Burnley employment exchange, before which, for the convenience of all concerned, workers appeared who were seeking release from employment for health reasons. This arrangement did not require his approval, except that the use of the employment exchange building had been allowed owing to the absence of other suitable premises. His Department did not compel workers to attend before this panel nor did it refuse to consider medical certificates from other doctors.

Home Guard M.O.s in Northern Ireland.—On July 6 Mr. MESSER asked the Secretary of State for War why medical officers in the Home Guard in Northern Ireland were granted only honorary rank while those in England were granted commissions. Mr. ARTHUR HENDERSON replied that for administrative convenience the Ulster Home Guard formed part of the Ulster Special Constabulary, and no question of granting commissions in the Army could arise until such time as that force was mustered, when it became an integral part of the armed Forces of the Crown.

Tuberculosis in Scotland.—The number of cases of tuberculosis notified in Scotland during 1938, 1941, and 1942 were:

	Pulmonary	Non-pulmonary	Total
1938	4,793	2,772	7,565
1941	5,739	2,555	8,294
1942	6,207	2,824	9,031

Mr. Johnston states that, comparing 1938 and 1942, all age groups show increases in varying degrees, the most marked increase being in the 15-25 age group.

Medical News

A course of six lectures on industrial health has been arranged by the Socialist Medical Association, and will be held at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C., on Wednesdays, from July 21 to Aug. 25, at 6 p.m. The lecturers are Drs. T. O. Garland, Donald Stewart, E. L. Middleton, Hugh Faulkner, R. S. F. Schilling, and Joan McMichael.

A conference on hospital meals has been arranged by the Food Education Society for Tuesday, July 20, at 3 p.m., at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C. The Minister of Health will take the chair and among the speakers will be Lord Horder and Sir Alfred Webb-Johnson, P.R.C.S. A film illustrating the dietetic treatment of rheumatism will be shown.

As a follow-up of the United Nations' Conference on Food and Agriculture, held at Hot Springs, U.S.A., the London International Assembly is holding a conference on post-war world food problems at the Livingstone Hall (opposite St. James's Park Tube Station) on Monday, July 19, at 2.30 p.m., with Viscount Cecil in the chair.

It is proposed to promote a Memorial Fund to the memory of the late Brigadier W. James Eastwood, who died at the age of 49 while holding the position of consulting orthopaedic surgeon in the Middle East. Those wishing to contribute to the fund should send donations to Mr. T. P. McMurray, Medical Institution, Liverpool, 3.

The Medical Section of VOKS, the U.S.S.R. Society for Cultural Relations with Other Countries, has issued a few numbers of a "Medical Chronicle." A limited number of stencilled copies of the fourth issue of this periodical (December, 1942) is available at 6d. a copy, post free, from the Anglo-Soviet Medical Council, c/o the Royal Society of Medicine, 1, Wimpole Street, London, W.1. This issue comprises nine typed foolscap pages, and there are brief reviews of such subjects as the "naphthalan" treatment of wounds, experience of naval physicians, utilization of the raw-material resources of the U.S.S.R., and reactions to air-raid alarms.

Dr. Angus A. Cameron is officially reported interned in Singapore. Official information has been received that Drs. C. C. B. Gilmour, O.B.E., D. M. McSwan, M.C., Hugh Smith, E. A. Struthers, and William Young (Kuala Lumpur) are interned in Changi Camp, Singapore.

In 21 years the Hospital Saving Association has raised £10,000,000 for the hospitals. Besides this routine work by which it helps contributors to avoid hospital bills, the Association has raised a special fund of £10,000 which will be used to provide scholarships for hospital nurses.

The Board of Education has issued to local education authorities Administrative Memorandum No. 468 (July 1, 1943) on the subject of school meals, laying down the procedure for the supply of kitchens, sculleries, and canteens by the Ministry of Works, together with a set of standard plans and a set of schedules of equipment.

Surgeon General Thomas Parran reports that since the outbreak of war the U.S. Public Health Service has given x-ray examinations for tuberculosis to nearly 250,000 people, and he foresees the possibility that with 20 portable x-ray units now in full operation 2,000,000 chest examinations would be completed during 1943. The U.S. Public Health Service has carefully studied the increase in tuberculosis mortality in Great Britain as a result of wartime conditions. In the United States slightly more than one in every 100 persons examined have significant tuberculosis of the lungs. Of these, between 55 and 60% are in the early stages most amenable to treatment, usually without sanatorium care. From 35 to 45% of the cases discovered by the Public Health Service are moderately advanced, and only 3 to 4% far advanced. The x-ray units employ portable 35-mm. photofluorographic equipment. Each is staffed by a medical officer, a technician, and a clerk, and has complete equipment for exposing and processing from 300 to 500 x-ray films per eight-hour day. Special attention is being given to shipyards, ordnance plants, air depots, and other essential establishments where no facilities for chest x-ray examinations are available.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In England and Wales notifications of measles and of dysentery fell by 698 and 57 respectively, but those of diphtheria and whooping-cough rose by 42 and 412.

The county totals of scarlet fever changed but little, and 6 fewer cases were notified for the whole country than in the preceding week. In the South and in London there was, however, a slight increase on the previous week; conversely, for diphtheria the increase was contributed by the North. The rise in the notifications of whooping-cough was general, the largest of the local increases being 91 in Lancashire and 33 in Staffordshire. Measles pursued an up-and-down course—down by 200 in Kent, by 97 in Essex, and by 79 in Suffolk; and (outstandingly) up by 89 in Buckinghamshire.

No fresh outbreak of dysentery was reported, and the number of cases declined by one-third during the week. In Lincolnshire, Scunthorpe M.B., notifications rose from 6 to 10; in Gloucestershire, Bristol C.B., from 8 to 14; and in London from 10 to 16. Dysentery has now persisted in Bristol for thirteen weeks, and a total of 121 cases has been recorded.

In Scotland notifications of dysentery rose from 56 to 108, and those of measles fell by 110. The rise in dysentery was general, the chief centres of infection being Edinburgh 30, Stirling county 17, Glasgow 15, Aberdeen 11. Fewer cases of measles are still being recorded: two-thirds of the notifications were from Glasgow 189, and Paisley 41.

In Eire the higher figure for whooping-cough resulted from outbreak in Westmeath, Coole R.D., where there were 19 cases. Of the 11 cases of typhoid 7 were reported from Cavan, Cavan R.D.

Statistics of Infancy

The statistics for the 126 large towns and for London separately for the first 26 weeks of this year indicate that the birth rate has risen and the infant mortality and stillbirth rates have decreased from those of the first half of 1942. The figures are:

	First 26 Weeks of Year			
	London		126 Large Towns	
	1942	1943	1942	1943
No. of live births	15,949	20,365	150,858	169,924
No. of stillbirths	595	568	5,997	5,932
Deaths age 0-1	1,083	1,221	9,449	10,110
Infant mortality	68	60	63	59
Deaths from diarrhoea under 2 years	130	219	933	1,253

The deaths from diarrhoea have risen by 34%, whereas the birth rate increased by only 13%.

The Week Ending July 3

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,984, whooping-cough 2,249, diphtheria 608, measles 4,165, acute pneumonia 530, cerebrospinal fever 49, dysentery 120, paratyphoid fever 10, typhoid fever 8.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended June 26, 1943.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included, London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease for: (a) The 126 great towns in England and Wales (including London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notified; a blank space denotes no return available.

* Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

† Includes puerperal fever for England and Wales and Eire.

‡ Owing to evacuation schemes and other movements of population, birth death rates for Northern Ireland are no longer available.

Letters, Notes, and Answers

communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1.

ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary is stated.

Those desiring REPRINTS should communicate with the Secretary of the Journal Board, B.M.A. House, Tavistock Square, W.C.1, on receipt of proof. Authors are requested to indicate on MSS. if reprints are required, and proofs are not sent abroad.

VERTICES should be addressed to the Advertisement Manager (Hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be sent to the Secretary.

PHONE NO.—B.M.A. and B.M.J.: EUSTON 2111.

GRAPHIC ADDRESSES.—EDITOR, *Antiology* Westcent, London; SECRETARY, *McIntosh* Westcent, London.

I.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

ANY QUESTIONS?

B Vitamins and Yeast

Q.—Current teaching seems to be that single vitamin deficiencies only occur. Where, for example, symptoms indicate a deficiency of one of the B vitamins, treatment should apparently consist in administration of the whole B complex and not the one vitamin lack which appears to give rise to the symptoms. Are all the B vitamins present in yeast? What is their concentration in, say, a yeast tablet supplied by the chemist? How many grains by weight should be prescribed in a suspected case of B hypovitaminosis? Any harm likely to arise through the continued use of yeast tablets? I have, for example, in his 1942 "Manual of Pharmacology," refers to the degeneration of rat testes produced by a yeast-containing diet.

A.—Some at any rate of the disappointment with vitamin therapy due to inadequate dosage. It is probably true that the individual members of the vitamin B complex work better when they are in association with each other, but at the same time it is difficult to get a therapeutic dose of vitamin B₁₂ without using a concentrate. At conclusion seems inescapable if we approach the problem on nutritive lines. All the B vitamins are present in dried yeast. *Charach* (*Food*, 1940, 9, 110) gives the following values per gramme dried yeast: vitamin B₁ (aneurin hydrochloride) 15 to 120 µg., nicotinic acid 550 to 650 µg., riboflavin 20 to 40 µg. The figure for riboflavin is given elsewhere as 65 µg. A 5-grain yeast tablet would contain a third of these values. *Bacharach* estimates the amount of dried yeast necessary to supply the normal daily requirement of vitamin B₁₂ at 1/4 to 7 oz. a day. It is therefore not really practicable to give even a maintenance dose of yeast in tablet form, and it is better given as brewers' yeast, bakers' yeast, or food yeast (*Torula* *lily*). Amounts up to 14 oz., equivalent to 120 5-grain tablets, can be given in this way, though anything above a teaspoonful t.d.s., as given in beef-tea or meat extract, is an effort. Dried yeast is a concentrated source of nitrogen and phosphorus as well as of vitamins. Disturbances of nutrition have occurred in growing pigs on as little as 4% of the daily ration consisted of yeast, though larger amounts than this can be tolerated if extra calcium is supplied. These and other grounds one would suggest that the safe upper limit of dosage of dried yeast in adult man was approximately 3 oz. a day. Therapeutic doses of vitamins are much larger than the maintenance requirements. *Brown* (*Proc. Mayo Clin.*, 1940, 15, 215) is the daily therapeutic dose of vitamin B₁₂ at 20 to 100 mg. orally, which is equivalent to 5 to 25 oz. of dried yeast a day! It would seem, therefore, that it would be neither practicable nor safe to treat hypovitaminosis B₁₂ by dried yeast alone. It would be wiser to try to get the best of both worlds by using a reasonable dose of dried yeast, not more than 1/2 oz. a day, plus a large dose of the pure aneurin hydrochloride.

Congenital Heart Disease

Q.—A healthy mother, now aged 29, has had three children: the first, born four years ago, was apparently a healthy female child, east-fed, but at 6 months old was found dead in her pram, having mitted her last feed. She had been left for only a few minutes. The second child, born three years ago, was a male and is in robust health. Two years ago the mother had a tubal pregnancy, which was removed at operation. The third child, a female, was born 8 months ago and has congenital heart disease; she gets periodic attacks of mitting after feeds, and at such times collapses and appears about to die. The question arises—Did the first female child suffer from detected congenital heart disease, and, if so, is it probable that the children will be liable to have the same abnormality?

A.—The data are not sufficient for any other than a tentative answer to be given. It is unlikely that the first child had undetected congenital heart disease, because it had had no symptoms before sudden death. It is unusual for more than one child in a family to have a congenital heart lesion. It is probable that patent ductus arteriosus is inherited and possible that other forms of con-

genital heart disease are hereditary, but little work has been done on the subject. The question is complicated by the fact that malformations of the heart are associated with arachnodactyly (incompletely dominant), transposition of the viscera (recessive), mongolism, and other defects.

Two Cases of Epilepsy

Q.—Can any suggestions be given for two patients approaching the menopause who have suffered for years from attacks of petit mal, associated with voidance of urine, causing naturally much annoyance and inconvenience? None of the usual remedies—phenobarbitone, "prominal," "epanutin," and "rational"—has relieved this distressing symptom.

A.—It is unusual to find epileptics in middle life who have attacks consisting only of a momentary disturbance with incontinence of urine and who have not responded to any of the phenobarbital or hydantoin group of drugs. The occurrence in two patients raises the possibility that the condition is not simply epileptic, since petit mal is usually fairly well controlled by adequate doses of these drugs. If there is no doubt at all as to the diagnosis, phenobarbital can be pushed to 2 or 3 grains a day, or can be combined with epanutin or a bromide mixture; but it must be remembered that the hydantoins do not control minor attacks so well as major ones. A simple bromide mixture with belladonna may well be more efficacious, and many chronic epileptics are well controlled by the following mixture given 3 times daily: sod. brom. gr. 7, sod. biborat. gr. 10, liq. arsen. m 3, and tinct. belladonnae m 5. As these two patients have already reached the stage of using the more expensive brands of phenobarbital it is likely that the more usual measures have been tried. It would consequently be advisable to make sure that no local defect of bladder control is present, either in the bladder itself, the urethra, or in an occult spina bifida. It is really very unlikely that if the incontinence is entirely due to epilepsy it will not respond to increasing doses of the anticonvulsants.

Pruritus in Pregnancy

Q.—I have a patient, 8 months pregnant, quite well and normal in every respect except for an intense generalized pruritus. The weight of the trouble falls on the hands and feet, which swell up and become warm and covered with an urticarial blush. So far I have tried various antipruritic lotions, calcium cum vitamin D injections i.m., and cool baths with sodium bicarbonate, without much success.

A.—Large doses of vitamin B₁₂ are most likely to be of help in this case, unless, of course, there has been some irritating factor apart from the pregnancy to account for the condition—e.g., if this patient has been doing a good deal of gardening it would be advisable to go carefully into the possibility of sensitivity to something handled there. If this source of urticarial reaction can be excluded, then the case would appear to be one of pruritus of pregnancy. I would suggest giving a basal sedative such as luminal gr. 1 once or twice a day, and an injection of vitamin B₁₂ 2 mg. daily. In spite of this the condition does not improve and is a source of sufficient distress to the patient it would be wise to induce labour. The condition should rapidly clear in the puerperium, probably within the first few days.

Sore Tongue

Q.—A single lady of 60 has suffered for six months from soreness of the tip of the tongue. There is very slight surface thickening there, but nothing else abnormal. The condition is getting no worse. She has applied lanoline without effect. She wears complete dentures; they are not irritant. What can be done?

A.—Soreness of the tongue in the absence of any local signs is sometimes related to a general condition—e.g., a severe anaemia. But in many instances no local or general cause can be found. These latter cases can be very troublesome and tend to occur particularly in older patients. The character of the pain is such as to suggest an ascending neuritis in the nerve supply—possibly arising from some long-forgotten and transient superficial inflammation. The slight surface thickening in the case under consideration may indicate this pathology. Some of the cases probably have a deficiency of vitamin B₁₂, so that it would be as well to provide all the B fractions, if necessary by injection. Nor should it be overlooked that the condition may be a neurosis underlying which is a cancerophobia. This not uncommon type is unfortunately often the outcome of anti-cancer propaganda campaigns. These cases should be reassured by examination at intervals, but in all cases local applications should be avoided as much as possible.

Ulcer on Lip

Q.—A man aged 60 has an ulcer on the left lateral portion of his lower lip, of two years' duration. The ulcer is oval in shape, with the long axis parallel to the lip—3/4 in. long by 1/4 in. broad, and situated entirely on the mucous membrane about 1/4 in. from the mucocutaneous junction. The ulcer is shallow, only the mucous membrane being deficient. The edges of the ulcer are regular; there is no induration at either the base or the edges. The base is of a

Mr. J. S. BATCHELOR (London, S.W.1) writes: The reply to question concerning the treatment of Morton's metatarsalgia (J 26, p. 808) makes no reference to the fact that certain and secure is provided only by operative treatment. So-called Morton's metatarsalgia is a condition in which acute lancinating pain, usually brought on by walking, occurs in the toes, commonly in the adjacent surfaces of the 3rd and 4th, of a foot which presents no special orthopaedic abnormalities. The number of therapeutic measures recommended in the answer is an indication of the characteristic ineffectiveness of such treatment. In practically every case Morton's metatarsalgia is caused by a neuroma of one of the digital plantar nerves of the foot, commonly the 4th. A simple operation for removal of the neuroma gives immediate relief. A full description of this condition, with an account of the operative treatment, is given by Betts (*Med. J. Austral.*, April 13, 1940, p. 514). It has been personally operated on a small number of cases with extremely satisfactory results.

NUTRITIONAL IRON DEFICIENCY ANAEMIA IN WARTIME

PART II

THE HAEMOGLOBIN LEVELS OF 3,338 PERSONS FROM BIRTH TO 55 YEARS OF AGE

BY

L. S. P. DAVIDSON, M.D., F.R.C.P.Ed.&Lond. G. M. M. DONALDSON, M.B., Ch.B.
S. T. LINDSAY, B.Sc. J. G. MCSORLEY, M.B., B.Ch., B.A.O.

(From the Department of Medicine, University of Edinburgh)

In a previous communication (Davidson *et al.*, 1942) we reported on Part I of this investigation—the haemoglobin levels of 442 infants and pre-school children (birth to 4 years) and 389 school children (5 to 12 years). We now submit data from a more extensive survey. All the haemoglobin examinations were made under standard conditions of technique and lighting by one member of the team who as had a very wide experience and whose ability to match colours is particularly good.

Since the publication of our previous paper a correction factor for the pipette, dilution tube, and colour tube of the Ialdane haemoglobinometer used has been supplied by the National Physical Laboratory. This correction factor varies with the haemoglobin readings—e.g., between the ranges 53 and 87% our instrument gives readings approximately 2% low. The correction factors have been applied to all the Edinburgh figures in the present communication.

This paper is concerned solely with the incidence of iron-deficiency anaemia. Investigations into the aetiological factors concerned in its production, and therapeutic trials for its correction, will be reported in a separate communication.

Infants and Pre-school Children (from Birth to 4 Years)

An additional group of 121 infants and pre-school children has been investigated, making a total of 563. The data obtained have provided no reason for materially altering the conclusions reached in the previous paper, that the Edinburgh series (1942) shows an improvement over the Aberdeen series (1935) (Davidson and Campbell, 1935; Davidson and Fullerton, 1938).

School Children (5 to 12 Years)

The number of school children investigated has now been raised from 389 originally reported to 1,022. Of these children 17 were examined at Edinburgh Education Authority primary schools, and came mainly from working-class families, while 105 were attending private schools and came from a much higher social and economic stratum of the population. The increase in the number investigated and the result of applying the correction factor necessitate a reconsideration of this group. Table I gives the average haemoglobin levels according to age and social status in Edinburgh school children, and Table II

TABLE I.—The Haemoglobin Averages of School Children according to Age and Social Status

		Age (Years)							
		5	6	7	8	9	10	11	12
Edinburgh:									
Municipal primary-school children	917	81.3% (61)	81.7% (118)	83.1% (118)	81.0% (139)	83.9% (143)	83.4% (155)	82.8% (116)	84.3% (67)
Private-school children	105	—	85.0% (8)	86.0% (10)	90.5% (4)	90.4% (18)	93.7% (17)	93.5% (22)	94.0% (25)

TABLE II.—Comparison of Anaemia in 3 Groups of School Children (5 to 12 Years)

Hb:		Percentage of Children in Different Haemoglobin Ranges			
		< 71%	71-80%	81-90%	> 90%
Edinburgh, 1942:					
Municipal primary schools	917	3.8	35.5	45.0	15.7
		39.3	—	60.7	—
Edinburgh, 1943:					
Private schools	105	—	4.7	38.1	57.2
		4.7	—	—	—
London: (Mackay <i>et al.</i> , 1942)	128	—	42.0	95.3	58.0
Aberdeen (Davidson and Campbell, 1935)	67	0	—	100.0	—

a comparison of the haemoglobin ranges of school children in Edinburgh (1942), London (1942) (Mackay *et al.*, 1942), and Aberdeen (1935) (Davidson and Campbell, 1935; Davidson and Fullerton, 1938).

Our previous acceptance of a haemoglobin level of 95±5 as the normal standard for the age group 5 to 12 years is supported by our finding that the average haemoglobin percentage of 105 children attending private schools was 91.7, and that 57% of these children had haemoglobin figures of 90 to 110%. The term "clinical anaemia" has been arbitrarily employed by us to connote a haemoglobin level of 80% or less in school children. On this basis 39% of municipal primary-school children and less than 5% of private-school children were anaemic. The conclusion reached in the previous paper that the haemoglobin level in children of working-class families of the age period 5 to 12 years is decidedly lower in Edinburgh (1942) than in Aberdeen (1935) still holds good. The average difference of 10% haemoglobin as reported in our previous article is now, however, reduced to 8%, when the correction factor for the haemoglobinometer is applied.

It will be noted in Tables I and II that a marked difference in the haemoglobin levels and ranges is found when the 917 children drawn mainly from working-class families are compared with the 105 children from the well-to-do classes. Accordingly the conclusion in our previous paper that economic status was no longer the principal factor influencing the nutrition of the individual must be reconsidered.

We have now repeated the haemoglobin estimations of children at two municipal primary schools examined in 1942, and it is of interest to note that the haemoglobin levels have improved during the past 12 months. Further investigations into this finding are being undertaken.

Haemoglobin Ranges of Adolescent and Adult Males and Females of Various Occupations

Table III shows the haemoglobin ranges of 1,753 individuals grouped according to occupation. The table is arranged in this way rather than according to age groups because of the wide variation in haemoglobin ranges found in persons of the same age group working and living under different conditions.

The schoolboys and schoolgirls (13 to 18 years) were attending private schools used by people of the well-to-do classes. The male and female students, the nurses, and the maids were all working in a large voluntary teaching hospital. The female factory-workers were employed in three different establishments. The 62 individuals in factory A were employed in a foundry, necessitating very heavy physical work. We

the factory medical officer as regards the particular need for iron, and the groups whose haemoglobin values are displayed in Table III represent an unselected cross-section of these employees.

Factory C consisted of a laundry in which 48 women were employed. Of the 123 male factory-workers working in factory B 85 had received no iron and 38 had had the supply

TABLE III.—Haemoglobin Ranges according to Occupation

	No.	<60%	61-70%	71-80%	81-85%	86-90%	91-100%	101-110%	>110%	Av. Hb.

were informed that the incidence of anaemia in this group was high, but, as will be seen from Table III, less than 5% were suffering from clinical anaemia (below 80% haemoglobin). The pallor of their faces, which was so noticeable, was apparently due to fatigue and not to anaemia. It should be noted that the majority of these workers had been employed in the foundry for only a few weeks before examination, and this might account for the wide difference in the incidence of anaemia in factories A and B.

ment of iron. As no significant difference in the haemoglobin levels in these two groups of males was found it was considered necessary to give the groups separately in the table. No beneficial effects would be expected from the iron supplement, since clinical anaemia was present to an insignificant degree. The haemoglobin levels of 45 multiparous women examined at factories A and B and at welfare centre are shown separately in Table III. The 570 pregnant women were examined at four separate ante-natal clinics in Edinburgh

in order to get a cross-section of the population. Their haemoglobin levels according to age are shown in Graph I and according to month of pregnancy in Graph II.

Incidence of Clinical Anaemia

In a leading article in the *British Medical Journal* (1943, 1, 449) doubt was expressed as to whether Price-Jones' (1931) figures of 98% for a female at 105% for a male should be accepted as normal standards of haemoglobin for the population as a whole. The figures which we have accepted as average normal, but not necessarily optimum standards are for females 95% \pm 5, and for males 100% \pm 5. We believe that the evidence afforded by this paper supports the contention that such standards can be maintained even under wartime conditions, since 50 to 70% of the females in the different groups examined have figures of 90% and higher, the average haemoglobin of 382 m was slightly over 100%. If haemoglobin levels of this magnitude are found at nearly four years of war with its concomitant dietary restrictions and difficult working conditions, then there is reason

GRAPH I.—Average haemoglobin levels from birth to 54 years in Edinburgh (1942-3) and Aberdeen (1935).

After arrangements had been completed for examining the haemoglobin levels of workers in factory B it was discovered that the factory medical officer had offered 10 gr. of Bland's pill daily to any worker who wished it. It was found that about 75% of the employees had been taking the iron supplement for at least three months before the haemoglobin levels were estimated. No selection of employees had been made by

to believe that average haemoglobin levels even higher than the proposed by Price-Jones might obtain in days of peace. In the same leading article it was also suggested that the term "anaemia in females" should be restricted to haemoglobin levels below 80%—a figure 15% below the standard accepted by us for normal women. We accept this definition as a basis for discussion although we realize that the level chosen is far

arbitrary. We would suggest on the same basis that a figure of 85% haemoglobin or less be accepted as the level of "clinical anaemia" in males. The haemoglobin levels lying between these figures and the normal standards suggested above would then be considered as subnormal. Although we are not aware of any evidence that such subnormal haemoglobin levels have any proved adverse influence on the well-being of men and women, we consider on general principles that it is unwise to be satisfied with figures below the accepted standards of normality.

GRAPH II.—Haemoglobin levels of pregnant women according to month of pregnancy.

With regard to what should be accepted as normal haemoglobin levels for pregnant women marked difference of opinion exists because of the influence of the varying physiological dilution of the blood which occurs with advancing pregnancy. According to Diekmann and Wegner (1934), a 5%, 10%, and 15% dilution of the blood takes place during the first, second, and third trimesters of pregnancy respectively. If a group of pregnant women in which approximately equal numbers are in the different trimesters be examined, then a deduction of 10% of the haemoglobin level should be made. On this basis "clinical anaemia" due to pregnancy may be said to exist when the haemoglobin level falls below 70%—i.e., 10% below the level of "clinical anaemia" in non-pregnant women.

Applying the above standards to the figures given in Table III, the incidence of "clinical anaemia" is found to be insignificant in female students and nurses, and varies from 6.6% in schoolgirls (13 to 18 years) to 21% in female factory-workers. The incidence of anaemia in 360 adolescent females (13 to 19 years) and 450 adult females (20 to 54 years) was 12% and 7% respectively. Approximately 60% of the total had a haemoglobin value greater than 90%. The incidence of "clinical anaemia" in 212 adolescent males and 170 adult males was less than 1%, and of these 95% had a haemoglobin level exceeding 90%. The incidence of "clinical anaemia" in 570 pregnant women was 24%.

Although it will be seen that a considerable degree of "clinical anaemia," as defined above, was present in school children and in certain groups of females, both pregnant and non-pregnant, it should be noted that the great majority of such persons made no complaint of ill-health and were apparently carrying out their work in the school, factory, or home in a satisfactory manner.

Comparison of Incidence of Anaemia in Edinburgh (1942) and Aberdeen (1935)

In assessing the effects of war conditions on the incidence of anaemia in the population at large it would be of great advantage to compare the findings of the Edinburgh survey (1942) with similar pre-war investigations. For accuracy in such comparisons it would be necessary to use a standard technique and to have the pipette and graduation and colour tubes calibrated and checked according to some accepted

standard, as was done in the present survey. It is most desirable that this principle should be generally accepted from now onwards. An attempt was made to obtain the instrument used in Aberdeen in 1935 in order to have it checked by the National Physical Laboratory, but unfortunately only the Haldane colour tube was available for testing. The correction figure supplied by the National Physical Laboratory shows that it gave readings approximately 2% too high. It is impossible to say whether this error can be accounted for by a slight fading of the colour tube during the past eight years or whether it was present in 1935. Since the pipette and dilution tube are not available for checking, it is impossible to assess the accuracy of the figures obtained in 1935. An extensive experience with the instrument concerned showed that haemoglobin figures of 100 ± 5 and 95 ± 5 for average normal males and females respectively were regularly obtained, together with a colour index of unity. Accordingly we believe that the instrument was in fact reasonably accurate. Hence we feel justified in making the following comparisons, provided the limitations discussed above are kept in mind. The Aberdeen figures shown on Graph I are the original uncorrected ones.

(a) The haemoglobin levels of infants and pre-school children in Edinburgh (1942) are slightly higher than those found in a similar age group in Aberdeen (1935).

(b) The incidence of "clinical anaemia" in municipal primary-school children in Edinburgh (1942) is considerably higher than in Aberdeen (1935).

(c) The incidence of "clinical anaemia" in adolescent and adult males in Edinburgh (1942) and Aberdeen (1935) is insignificant, but the haemoglobin levels are somewhat higher in the Edinburgh series.

(d) No significant change was observed in the haemoglobin levels of adolescent and adult females examined in Edinburgh (1942) and in Aberdeen (1935). Thus a haemoglobin level of less than 85% was found in 23% of 306 adolescent females and 18% of 450 adult nulliparae in Edinburgh, as compared with 18% of 450 adolescent females and 25% of 50 adult nulliparae in Aberdeen.

(e) The haemoglobin levels of pregnant women examined in Edinburgh (1942) are slightly lower than those of a similar group examined in Aberdeen (1935).

Summary

The haemoglobin levels of 3,338 individuals examined in Edinburgh in 1942-3 are reported. These comprise: 563 infants and pre-school children (birth to 4 years); 917 municipal primary-school children (5 to 12 years); 105 private-school children (5 to 12 years); 518 adolescent males and females (13 to 19 years); 620 adult males and females (20 to 54 years); 45 multiparous women; 570 pregnant women.

The pipette, dilution tube, and colour tube of the Haldane haemoglobinometer used in this investigation were examined by the National Physical Laboratory and a combined correction factor was supplied. This factor has been applied to all the haemoglobin figures of the Edinburgh series shown in the tables and graphs of the present communication.

Standards of normality of haemoglobin levels for individuals according to age and sex are discussed and defined, and arbitrary figures below which clinical anaemia may be said to be present have been selected.

"Clinical anaemia" was found to be present in 39% of municipal primary-school children; approximately 5% of private-school children; 12% of adolescent females; 7% of adult females; 24% of pregnant women; and less than 1% of adolescent and adult males.

We wish to express thanks to our medical colleagues, to the Medical Officer of Health for Edinburgh and his staff, and to the head masters and staffs of schools for the facilities and help afforded during this investigation.

CHILDHOOD INFECTION AND ITS RELATION TO ADOLESCENT AND ADULT PULMONARY TUBERCULOSIS

A RECORD OF THE WORK OF THE BROMPTON HOSPITAL
RESEARCH DEPARTMENT DURING THE LAST 14 YEARS

PREPARED BY

A. MARGARET C. MACPHERSON, M.D., M.R.C.P.
Halley Stewart Fellow, Research Department, Brompton Hospital

[Drs. G. E. Beaumont, Dorothy Cooper (née Dow), Maurice Davidson, J. L. Livingstone, W. Ernest Lloyd, A. Margaret C. Macpherson, R. C. Wingfield, and F. H. Young have from time to time been responsible for or associated with the various investigations of the Brompton Hospital Research Department during the past fourteen years. They may be regarded, therefore, as signatories of this paper, but cannot hold themselves accountable, each and severally, for all the views expressed and for all the conclusions reached in this collected record.]

On March 21, 1928, the Medical Committee of the Brompton Hospital decided to promote and encourage research at the hospital by (1) the organization of a research department, and (2) the institution of a research fund. The Research Department accordingly came into being. Apart from the other activities covered by its constitution, it was felt that the problem forming the title of this paper was one which should be studied. A subcommittee of the staff (whose personnel has changed from time to time) was therefore appointed; suitable assistance was obtained with the help of the Research Fund, and the investigation was started. To the generous contributors to the research fund our thanks are due, but in particular to the Sir Halley Stewart Trust, all of whose contributions have been devoted to this special piece of work. The investigation is not yet finished; it may be years, if ever, before it is, but it is felt that enough has already been done to justify (1) a summary of the results from the various reports published to date; (2) an indication of the lines on which the investigation is proceeding at the present time.

Childhood tuberculosis was the subject studied for the most part when the department was first opened, and we believe that our findings have to some extent helped to build up the picture of this condition as it exists to-day. This aspect of tuberculosis is still prominent in the work of the department, and observation of the children continues. The number of children seen up to the present is 2,482. At the same time, during the fourteen years attention was constantly focused on the disturbing problem of tuberculosis in young adults—a problem of such importance at the present day, and promising to become of increasing urgency in the near future, that it calls for immediate recognition, and the need for more definite observations on the subject, we set ourselves to investigate certain of its aspects. These investigations have brought to light some interesting facts and have led to our present study of treatment of symptomless pulmonary tuberculosis in young adults. Although as yet we cannot provide any definite results of treatment, we consider the matter to be of sufficient immediate interest to justify the publication of the way in which we are tackling the question.

The first task undertaken by the Research Department was the elucidation of some of the problems of childhood tuberculosis which at that time were still obscure. No appreciable amount of work on this subject had been carried out in this country. Among the established facts about childhood tuberculosis were the figures of the mortality rates, which showed a great fall during the present century. It was decided to analyse the figures for this period, and this formed the substance of Report I.

Report I (1930): "Tuberculosis Mortality in Children" (Lloyd and Dow, 1932a)

Analysis of the mortality rates from tuberculosis in children for the period 1898 to 1927 in England and Wales brought out the following interesting facts:

1. The decline in the mortality rate was greatest for children under 5 years old.
2. The rate of fall due to abdominal tuberculosis was greater than the rate of fall due to other forms, and in 1927 meningitis was by far the most fatal form of tuberculosis.
3. Although the mortality rate due to tuberculosis was greater in infancy than in later childhood, when taken in relation to the mortality rate from all causes tuberculosis is a much less frequent cause of death in young children than in those approaching adult life.
4. Before 1914 the 0-5 years age group had the highest tuberculosis mortality rate; since 1914 the tuberculosis mortality rate has been consistently higher in young adult life and middle age than in the 0-5 years group.
5. With the decrease in the mortality rate due to tuberculosis in the 0-5 years group the mortality peak in adult life changed from the 40-50 years group to the 20-25 years group.
6. The importance of exposure to tuberculous infection was demonstrated clearly by the fact that among the families attending Brompton Hospital there was a definitely increased death liability from tuberculosis in children aged 0-5 years who were brought up in contact with open cases of tuberculosis.

This report, while emphasizing the improved position of tuberculosis in childhood, underlined the continuing and relatively increasing menace of young adult tuberculosis. This was a problem that was continually demanding recognition and suggested further investigations, which were begun at this time but were reported at a later date.

In the meantime, the connexion between exposure to tuberculous infection and mortality due to the disease in infancy was an important finding which could with benefit be investigated still further and which might lead to solutions of practical value. If deaths from tuberculosis in childhood were related to exposure to infection, what was the relation between contact history and tuberculous morbidity in the living child. In other countries extensive tuberculin-testing had been carried out in the childhood populations. The results of these tests showed that, although the actual figures varied considerably in different countries and localities, the number of positive reactions to tuberculin was high in children exposed to infection when compared with those with no known contact infection. It was thought that a similar investigation carried out in this country might be of value, and this was the piece of work undertaken by the department.

Report II (1931): "The Incidence of Tuberculous Infection and its Relation to Contagion in Children under 15" (Lloyd and Dow, 1931, 1932b)

During 1930 and 1931 1,220 children attending the out-patient department at the Brompton Hospital were subjected to a tuberculin test. A comparison was first made between the two methods in vogue in Europe, Scandinavia, and the U.S.A.—namely the Pirquet test and the Mantoux intradermal test. The results showed that the Mantoux was the more accurate, and that the Pirquet about equivalent to the Mantoux using 1 in 10,000 dilution of tuberculin.

The results among this group of the population corresponded with those of observers in other countries and demonstrated certain important facts. Taking the children

FIG. 1.—Percentage of children who reacted to the Mantoux test, arranged according to age and sex groups.

whole, there was a steady increase in tuberculous infection from birth to 15 years of age (see Fig. 1). If, however, the children who had a history of exposure to an open case of tuberculosis were separated from those with no known contact the results were very different. It was found that the number of positive reactors was almost doubled in the contact group taken as a whole compared with the non-contact group. The difference was still more marked in younger children, the number of positive reactors being five times greater in children under 5 years old in the contact group than in the non-contact group (see Fig. 2).

FIG. 2.—Percentage of contact and non-contact children who reacted to the Mantoux test, arranged in age groups.

The significance of direct contact with the tubercle bacillus was further stressed by the fact that the results of tuberculin-testing a group of children with no history of contact scarcely differed from the results obtained in a group of children with a history of contact with a closed case of tuberculosis (Fig. 2).

Although these facts had been established in other countries the results in this report were among the earliest published in England to show the importance of the connexion between contact with open cases of tuberculosis and tuberculous morbidity in children. The findings underlined the importance of contact history; the previous report had shown its importance in relation to tuberculosis mortality, and this later investigation its importance in relation to tuberculous morbidity in the living. The tuberculin test had provided us with valuable evidence of tuberculous infection in the living, and apparently healthy, child: was there any means of demonstrating, and possibly resting, the tuberculous lesion resulting from this infection? The low rate of mortality in childhood compared with the higher rate of morbidity gave little hope of help from clinical findings, but x-ray investigation might bring to light valuable information. Such investigations in the U.S.A. were creating much interest, and it was decided to make a systematic examination of tuberculin tests and x-ray findings in the children in the out-patient department at the Brompton Hospital.

Report III (1932): "A Comparative Study of X-ray and Mantoux Reactions in Children" (Lloyd and Dow, 1932c, 1932d)

During 1930 and 1931 500 children under 15 years of age were examined clinically and radiologically and had a tuberculin test. In order to assess the value of the radiographs without prejudice, the chest was examined and reported on without previous reference to the Mantoux reaction. This investigation made manifest the difficulties of interpretation of radiographs in children, and the conclusion was reached:

"that in attempting to localize the lesions in children who are shown to be tuberculous by a positive Mantoux reaction, the chest radiograph is not so helpful as might have been supposed. . . . While the chest radiograph is of great clinical value . . . its interpretation in the 'Mantoux-positive' child needs the greatest care."

Although the interpretation of these radiographs was difficult, it was evident that typical lesions of the adult type of pulmonary tuberculosis were comparatively uncommon in children under 15 years of age.

In order to keep in touch with this large group of interesting children a "follow-up" department had been by this time established, and it was possible during the ensuing years to

augment the findings of these last reports. There are now 989 children who have attended the follow-up clinic for a period of from 2 to 13 years; of these 756 are "contact" children, and the rest continue to attend either as controls or because they have evidence of tuberculous lesions. While the children are still in contact with cases of tuberculosis they come for examination at least once in every three months. After contact with infection has ceased and there is no evidence of any active tuberculous lesion the attendances are extended to once in six months.

Report IV (1933): "Reinvestigation of Mantoux-positive Children" (Lloyd and Macpherson, 1933a, 1933b)

After an interval of 1½ to 2 years 700 of the children included in Report II were subjected again to the Mantoux test. It was found that the great majority (96%) of the positive reactors in 1930 remained positive in 1½ to 2 years' time. There was, however, a change during this period in the degree of sensitivity: those who at the first testing reacted only to the stronger doses tended to become more sensitive. The figures also showed that a high degree of sensitivity was reached at an early age in contact children, whereas in the majority of non-contact children this degree of sensitivity was not reached at any age during childhood.

Throughout this and the subsequent investigations very few cases of active pulmonary tuberculosis were met with, and, in fact, obvious clinical tuberculosis among the children was conspicuously low throughout our observations.

In Report III the difficulties encountered in the interpretation of chest radiographs in children were described, and these, together with many diagnostic problems which made their appearance while observing the children in the "follow-up" department, showed the necessity for a more detailed study of the course of childhood tuberculosis. Between 1930 and 1939 considerable material had become available in the department, and by means of serial radiographs over a period of years it was possible to solve some of the problems which had presented themselves at the beginning and to build up a picture of the primary tuberculous lesion in childhood.

Report VII (1939): "Primary Tuberculosis of the Lungs in Childhood" (Macpherson, 1939a, 1939b)

This report contained a description of the primary tuberculous lesion of the lung and its subsequent course as it appeared among the children in the follow-up department. It was noted that the normal course of the primary lesion was usually uneventful and was unattended by clinical symptoms or signs, and in most cases was evident only in the x-ray film. Attention was drawn to the fact that the process of healing occupied more than one year and that throughout this period the focus was a potential source of dissemination. It was stressed that during this time it was advisable to facilitate healing by procuring a suitable environment for the child and to keep a close watch on the progress of the lesion.

Another characteristic of the primary complex was the relative unimportance of the lesion in the lung tissue compared with the lesions in the lymph nodes. It was these infected lymphatic glands which were more likely than the lung lesions to produce complications and to give rise to clinical evidence of disease. The relation between the glandular involvement and subsequent atelectasis and bronchiectasis was discussed. In only one case—that of a girl infected between the ages of 13 and 15 years—was the primary lesion seen to spread and to give rise to fibro-caseous disease of the adult type. The pulmonary lesions otherwise tended to heal by fibrosis or calcification.

So far the work carried out on childhood tuberculosis had demonstrated clearly that:

1. Primary infection by tubercle bacilli usually is uneventful clinically and the lesion formed heals satisfactorily in most cases.
2. Certain immediate and later complications may, however, arise, as a rule secondarily to the involvement of lymphatic glands in the primary complex.
3. Tuberculous meningitis has been, and still is, a serious outcome of tuberculous infection.
4. Tuberculous morbidity and mortality in childhood are markedly influenced by exposure to infection.
5. The "adult type" of tuberculosis does not present a serious problem in childhood.
6. Relatively to pulmonary tuberculosis in childhood, and even to tuberculous meningitis in childhood, pulmonary tuber-

culosis in adolescence and early adult life is a greater menace to the population.

The mortality rate from pulmonary tuberculosis among young adults showed little evidence of decreasing, and the matter continued to cause great concern. Here, then, was a subject bristling with problems for further elucidation and asking for a direct and immediate attack. Obviously it would be of immense value to establish a definite aetiological connexion between childhood infection and tuberculous disease in later life, but such an undertaking would require much material and occupy many years before there was any hope of providing a full and definite answer. However, the large numbers of observations we had been able to make in the follow-up department supplied us with some interesting evidence which to a certain extent indicated the relation between childhood infection and adolescent pulmonary tuberculosis. As some of those under observation passed from childhood to adolescence, adult types of lesions began to appear, usually between the ages of 15 and 19.

These lesions were as a rule localized to the upper third of the lung. In the majority of cases they were not accompanied by any clinical disturbances or by loss of weight, and in some instances there was not even an increase in the sedimentation rate. If left untreated the lesion showed a "pendulum" action, alternating between a spread of the lesion and healing, but nearly always with a tendency to spread and seldom healing spontaneously. The period of time between the first appearance of the lesion in the x-ray film and the first symptoms varied between three and five years.

These observations led us to a closer study of pulmonary tuberculosis in the young adult, and the next report dealt with the problem of contact history in pulmonary tuberculosis of young adults.

Report VI (1937): "Pulmonary Tuberculosis in Young Adults: The Significance of Contact History" (Lloyd and Macpherson, 1936, 1937)

Report VI contained an analysis of the family histories of 1,000 patients at the Brompton Hospital who had developed pulmonary tuberculosis between the ages of 15 and 25. The fact that there was a history of contact with tuberculosis before the onset of the disease in 40% of the cases was significant. Among those with a family history of tuberculosis, contact with a tuberculous brother or sister was found to be as frequent as contact with a tuberculous parent. Four out of five of the patients who gave a history of contact developed the disease within five years of the exposure to the last known contact with infection. This report again stressed the importance of contact history, and the conclusions also suggested that reinfection in adolescence or early adult life might play an important part in the onset of young adult lesions.

Another aspect was constantly making itself apparent: the advanced stage of tuberculosis reached before treatment was begun or was even sought by the young adult. To quote from the introduction to Report V: "Too many patients do not seek treatment until their disease is well entrenched. This is no doubt a fact is the reason why our tuberculosis service spends most of its energies, time, and money in endeavouring to patch up hopelessly damaged individuals by preventing further activity and inroad of the disease."

Those entrusted with the care and treatment of these young adults were repeatedly putting forth pleas for earlier diagnosis. But the fact remained that examination immediately after the first symptoms of early pulmonary tuberculosis were detected often showed considerable lesions in the x-ray films.

A hypothesis was formed "that perhaps the extensive lesions of adult disease are really in many cases deposited during adolescence with the accompaniment of slight or, at any rate, unexplained constitutional disturbance: that these lesions are carried unrecognized, perhaps extending slowly and without symptoms, until they make their presence known in adult life, either by reason of their spread past a definite point or because some environmental cause has allowed of their reactivation"; and our hitherto unpublished observations from the follow-up department on the symptomless lesions of adolescence (see above) tended to strengthen this hypothesis.

The testing of the hypothesis involved the radiological exami-

Report V (1936): "Latent Adolescent Pulmonary Tuberculosis" (Wingfield and Macpherson, 1936a, 1936b)

During 1934 and 1935 such an investigation was undertaken on 2,381 young people between 14 and 21 years old, healthy at the time, who were examined and the first record of mass radiography of a sample of the English population was published in 1936.

The results of this investigation showed that there was an incidence of pulmonary tuberculosis in 0.65% and a possible incidence in 1.08% of our sample of the adolescent population. A comparison between these figures and the calculated incidence of pulmonary tuberculosis in the population (0.4 to 0.75%) supported the hypothesis set forth above. Here, then, was evidence of detecting at a really early stage adolescent lesions which would give rise to clinical disease, and a means of providing clinicians with material at a stage in which treatment should be easy compared with well-established lesions which they can do little but only to arrest.

It was not overstating the case when it was remarked in Report V: "The significance and implications are tremendous." The report ended with a plea for further more extensive investigations.

This was in 1936. It has taken much education and propaganda, directed during the ensuing years to the medical profession and the lay public alike, to bring about the development and application of the suggestion put forward at that time. Mass radiography is a necessary weapon for the detection of pulmonary tuberculosis at a stage in which treatment, from the patient's point of view, could be of real value and, from the point of view of the State, far more economical than later. It has been encouraging to find that recent examination by mass radiography with more accurate apparatus and in more satisfactory conditions have produced results very similar to ours.

Since this report on latent adolescent primary tuberculosis and following on the observations, to which reference has already been made, on the development of these lesions those attending the follow-up department, attention has been constantly focused on the problem of treatment of those patients without symptoms but with radiological evidence of disease. Recognizing that this would become a major problem should mass radiography be adopted, it was obviously necessary to examine the possibilities of adequate treatment from the point of view of healing the lesion and from the economic standpoint.

A healthy youth, working and playing hard, with no symptoms, is suddenly singled out from his companions and found that he has evidence of pulmonary tuberculosis. The first and very real difficulty is to persuade the boy or girl that investigations are necessary. Fortunately, as a result of propaganda on the value of radiological examinations, becoming easier, but it is often more difficult to persuade the patient's doctor to take the matter seriously. These difficulties overcome, the patient is usually admitted into hospital for investigation. It is not uncommon that, apart from the x-ray graphs, every finding is normal; there may be no abnormal physical signs, no pyrexia, a normal blood sedimentation rate and normal gain in weight.

According to the hypothesis propounded in Report V, adolescents are the very people who eventually will develop manifest disease. It is therefore folly to continue observation without treatment in the hope that the case in point is the exception which proves the rule. This course is desperately advocated by the boy or girl and the parent, unfortunately is too often adopted by the doctor in consultation. In some cases on our records the patient won the battle; treatment was postponed until symptoms appeared, with the result that only a "patching-up" of the individual was possible. The value of the early x-ray examination had been entirely lost. Healing, surely, and not just temporary arrest, should be the aim, and should be the aim when these early lesions are under consideration.

Some form of treatment, therefore, is called for, and at an early stage the economic factor comes into prominence and influences the course followed. At the present time such cases when detected, are handled in one of the four following ways: (1) they are either ignored or are merely observed for a period; (2) they are kept under careful observation, with impro-

their home environment; (3) they are sent to a sanatorium; they are, in only a few instances, treated by artificial pneumothorax.

Treatment of Symptomless Adolescent Pulmonary Tuberculosis

For those who can afford the time and treatment it is probable that with rest at home, followed by gradually increasing activity and then by years of sheltered life, healing may take place. It is, however, only a favoured few who can afford this; for the majority a more rapid return to work is necessary. Moreover, it is unusual to find any person who, while apparently in good health, will submit to this treatment and at the same time retain a healthy outlook on his "illness," or the capacity to return to a normal life at the end of it.

For the majority, therefore, some other course is advised. Sanatorium treatment is the usual one adopted for these patients. Owing to the healthy condition of the patient on admission to the sanatorium and the constant urge to get home and back to work, it is usually impossible to keep him or her at the institution long enough to hope to effect a cure. There may be a temporary improvement in a few cases, but in the majority there is no material change in the x-ray picture, and the expected spread of the disease comes sooner or later at a variable interval.

It seems that artificial pneumothorax provides a more satisfactory prospect; we believe that this is the correct treatment in these cases, and it is the one which has been adopted. These symptomless patients should be ideal subjects for such treatment. As they have no constitutional disturbance it does not matter that they require prolonged bodily rest at hospital or sanatorium. Some measure of local rest to the lung is produced by a pneumothorax, and it is not necessary to attempt complete collapse of the lung: a shallow pneumothorax sufficient to control and immobilize the diseased lung, partially or completely, is what is required, and it is suggested that the pneumothorax be maintained for not longer than two or three years, by which time, on the analogy of the tuberculous joints, the hoped lesion will have healed. A shallow pneumothorax for a slight lesion of the lung is unlikely to give rise to complications, and causes no discomfort or subjective incapacity.

Once the collapse is established daily supervision is not necessary, and, provided that the home conditions are good, the patient need only stay in hospital for a short period. Where the home is unsatisfactory, or the patient's general condition below normal, a period in a sanatorium may be necessary. A number of our patients have returned to work or school without any ill effects a short time after the induction of the pneumothorax. If the infiltration is bilateral the position is altered and the treatment is the same. A shallow bilateral artificial pneumothorax is tolerated as easily as a unilateral one, and in the case with a unilateral artificial pneumothorax there should be no hesitation in inducing a bilateral artificial pneumothorax should a tuberculous deposit appear in the other lung.

Regular supervision is ensured by the weekly attendance refills; and this is important, because without such a tie the young people will naturally tend to become less and less frequent in their attendance over a period of years.

Here, then, is a form of treatment which offers a reasonable prospect of cure without prolonged exile from normal life and work. We would emphasize that, as yet, it is impossible to assess its value, but we suggest it as a reasonable alternative to other methods in use which, in our experience, are unsatisfactory in their final results or are impracticable for the majority of patients.

PERIPHERAL ARTERIAL EMBOLISM

BY

H. AGAR, F.R.C.S.

Major, R.A.M.C.; Surgical Specialist

The surgical treatment of embolic occlusion of a peripheral artery has been developing over a long time. In 1907 both Sampson Handley and Moynihan attempted to relieve the condition by operation. In this country little attention was paid to their efforts, but the Scandinavian surgeons, led by Einar Key, developed a satisfactory operative technique, and in 1925 Jefferson performed the first successful embolectomy in England.

The incidence of embolic occlusion it is impossible to assess, but, although the condition is not common, I believe many cases are missed. Griffiths (1938) reports 8 cases in a three-year period in Manchester; and in St. James's Hospital, Leeds, from 1936 to 1939, with approximately 28,000 admissions, there were 7 cases in 5 patients, all of which came under my care.

The embolus may arise from the pulmonary veins, a vegetation on the mitral valve, a mural thrombus of the left auricle, or an atheromatous plaque of the aorta; or from a systemic vein in the presence of a patent foramen ovale. The cardiac origin is by far the commonest, and is often associated with auricular fibrillation. It was the focus in all my cases. Emboli usually become impacted at the bifurcation of an artery, for it is here that the lumen is most suddenly reduced in size. Of 382 Swedish cases (quoted by Riddell, 1937) the embolus was located in the common femoral in 54%, in the common iliac in 17%, in the popliteal in 11%, in the upper limb in 12%, and in the aorta in 4.5%. The few cases operated on in England suggest about the same percentages, and in my series four of the emboli were impacted at the bifurcation of the common femoral artery, two in the popliteal, and one at the bifurcation of the aorta.

Diagnosis

Diagnosis is usually easy, and depends on pain, pallor, paralysis, and loss of arterial pulsation in a limb. It is reported that immediately the artery is occluded the patient complains of sudden severe pain, often located over the site of the embolus. This description is inaccurate, for although pain may be severe it may also be absent. None of my patients complained of severe pain and only four of slight pain. In the case of occlusion of the bifurcation of the aorta the operative findings indicated that most probably the blockage had been sudden and complete; for there was no secondary thrombus, and yet the patient did not complain of real pain but only of abdominal discomfort. Deitch (1936) speaks of "agonizing colicky pain," and Riddell of "intense agonizing pain." The intensity or absence of the pain therefore must not influence the diagnosis.

All my patients did complain of numbness and loss of use in the affected limb. In five in whom the incident occurred while they were in hospital undergoing treatment for auricular fibrillation it was the first complaint to be made to the ward sister. The circulation was probably impaired for a few minutes before nerve symptoms appeared. In a case of occlusion at the bifurcation of the common carotid Griffiths (1938) reports sudden contralateral hemiplegia. A general pallor with some blotchy cyanosis was observed in all the affected limbs and was present within a short time of the first complaint by the patient. The limbs felt colder than the normal, and the area of anaesthesia was of the stocking type but not reaching as high as the site of impaction.

There is always loss of arterial pulsation beyond the blockage, but this may be misleading in the case of obstruction at the bifurcation of the common femoral artery. The common femoral artery is 1½ in. long, and, to the unwary, palpable pulsation below Poupart's ligament may give the impression that the femoral arteries are patent and that the blockage is in the popliteal. I found that if a sphygmomanometer cuff was applied round the mid-thigh no oscillations in the mercury column were visible at any pressure in cases of femoral blockage, but that they were easily seen in cases of popliteal

blockage. A more accurate instrument is the Pachon oscillograph, but it is rarely available.

Whether this group of signs and symptoms occurs rapidly or slowly should not affect the diagnosis, which it is important to make as early as possible.

Leriche, Fontaine, and Frich in 1933 urged the use of thorotrast in diagnosis and in localization of the embolus, but although this method may be very accurate I feel that it should be rarely necessary.

Treatment

Opinion regarding the best treatment varies from non-operative conservation to removal of the affected part of the artery. Leaving the patient may result in spontaneous recovery, or by chance the embolus moves into a side branch of the artery, but it is more likely that he will die rapidly or after the onset of gangrene. Murray (1936) has experience of 13 cases which were not operated upon; 8 of these patients died before the onset of gangrene, and the others afterwards.

Embolectomy is not universally favoured, the dissenters claiming that it does not restore circulation in a sufficiently large proportion of cases and that too many patients fail to survive. Strömbeck (1935) reviewed 327 operations and found that 63% of the patients died in hospital and only 12% survived for five years. In spite of the failures many cases are outstandingly successful. It is accepted that patients rarely die from the operative intervention; all my cases were suffering from auricular fibrillation, yet there was no operative mortality. The patient with aortic occlusion stood the operation surprisingly well; the circulation in his leg recovered, and he survived for several months. Another patient on whom I performed a femoral embolectomy was doing her full housework one year later. Embolectomy is rarely contraindicated by the poor condition of the patient, and if performed within six hours there is a reasonable chance of success, but if after twelve there is practically none. Surgeons are therefore very largely dependent upon the general practitioner and physician for the successful treatment of the condition.

Anaesthesia was induced by spinal percaine 1/200 for all except the aortic case, for which it seemed better to use the 1/1500 solution so as to make the Trendelenburg position safer. Local anaesthesia is efficient and safe, and is of particular value when operating on the brachial and subclavian arteries. A special advantage is that the patient can describe subjective sensations, which are useful in assessing any recovery of circulation during the operation.

Operative Technique

The affected artery is approached through one of the usual incisions, and I stress that the bifurcation of the femoral is more distal than often imagined. Recent opinion has been that an aortic embolus should be milked down from the bifurcation after retroperitoneal exposure and removed through a femoral artery previously prepared but temporarily closed distally by a rubber band. I approached the aorta transperitoneally and found no difficulty. There was no unusual distension of the gut, and the patient withstood the operation extremely well. This is, I believe, the tenth successful aortic embolectomy, and of these cases four have been approached transperitoneally.

The site of the embolus is located by the cessation of pulsation. A sling of rubber tubing is placed both proximal and distal to the embolus. The proximal one is rendered taut and an incision made in the artery over the embolus. This is gently lifted out, and it usually brings with it a length of secondary thrombus; in one femoral case 8 in. of thrombus was removed. If the distal band is made taut before this stage the secondary thrombus may be broken and part of it pass along to block the artery more distally; this I believe is an important point in technique. For the same reason I think an artery which is being opened distal to the embolus—for example, a femoral in a case of aortic occlusion—should not be lifted by the slings until it is seen to be free from secondary thrombus. I found suction applied through a Eustachian catheter passed into the artery useful in removing distal thrombus. If completely cleared there should be some bleeding from the distal end.

The distal sling is then lifted and the proximal one released, the blood pressure is usually sufficient to clear this part

of any remaining fragments. Then both slings are lifted, the wound is bathed in sodium citrate 3%, and the artery was quickly sutured with waxed Chinese silk size 0, the stitches passing down to but not through the intima. It is surprising how few stitches are required.

This was the technique followed in my cases, including the aortic, in which the slings were placed around the aorta and common iliacs while the incision was made just above the bifurcation.

If the distal circulation shows no signs of recovery within one hour a more distal exploration of the artery must be considered, but it should be remembered that circulation may improve without recovery of peripheral pulsation.

Other operations described for the relief include ligation of the artery above and below the incision after removal of the embolus, the intention being to prevent post-operative thrombosis. A more radical device is the excision of the affected part of the artery, it being maintained that complete section of the artery prevents spasms and tends to open up the collateral circulation.

I have no experience of the post-operative use of heparin but it seems probable that this may prevent post-operative thrombosis in the affected vessel. The dosage recommended is 10 units of heparin to 1 c.cm. of saline given by intravenous drip at the rate of 25 to 30 drops a minute, or 1,500 in four-hourly if given intermittently.

Summary of Cases

Case 1.—Man aged 57, admitted Dec. 18, 1936, with auricular fibrillation and mild cardiac incompetence. Cardiac condition improved but fibrillation persisted. On March 6, 1937, there was sudden onset of numbness without pain in right leg. Five hours later, when first seen by me, the signs of occlusion of the popliteal artery were typical. Under spinal anaesthesia an embolus was removed through the popliteal artery from the level of the adductor hiatus. No thrombus could be extracted from the distal point. The circulation did not recover and amputation became necessary. There may have been a more distal embolus or the thrombus may have broken away during the exposure of the artery. It might have been better to excise the affected portion of the artery, but chance of recovery must have been remote.

Case 2.—Man aged 64, admitted Nov. 30, 1938, with auricular fibrillation, palpable liver, and basal pulmonary congestion. Dec. 5 he developed a typical occlusion of the left femoral artery without any pain. The embolus with three inches of thrombus was removed under spinal anaesthesia three hours later, and the circulation of the limb recovered completely. On Dec. 9 the popliteal artery became blocked and an embolus was removed. The circulation did not recover, and the next day he developed a paralysis of the right arm, followed in twelve hours by a hemiplegia and he died. The terminal signs were probably due to a block with spreading thrombosis in the cerebral circulation. No necropsy was granted.

Case 3.—Woman aged 53; she had several transient attacks of pain and loss of use in the left leg and arm and right leg. Admitted Feb. 5, 1939, fourteen hours after the onset of pain and loss of use in right leg. Auricular fibrillation was present, but the evidence of failure was albuminuria. A diagnosis of femoral embolism was made and an embolus was removed, but no thrombus could be extracted and there was no bleeding from the distal end. Gangrene developed, necessitating amputation. The cardiac condition improved and she went home on April 6. On April 12 she was readmitted with a right femoral blockage of six hours' duration. The embolus with four inches of thrombus was removed. The circulation was almost normal after twelve hours, but became deteriorated again, with the development of gangrene. A rapidly increasing bacterial endocarditis appeared, and the patient died on May 4. Necropsy was granted, but I think a secondary thrombosis may have caused the failure in the second embolectomy.

Case 4.—Man aged 28, admitted April 5, 1939, because of dyspnoea, cough with blood-stained sputum, and oedema of the legs. A diagnosis of auricular fibrillation with failure was made. He was given digoxin 0.25 mg. t.d.s., and his pulse, though still irregular, improved. On April 13 he suddenly complained of numbness of both legs and a little abdominal discomfort. When seen on April 14 there was a blotchy discoloration below the knees, with loss of both legs and anaesthesia of stocking type reaching above the knees, and no femoral pulsation. A diagnosis of occlusion of the bifurcation of the aorta was made. He was operated on under spinal percaine anaesthesia. The embolus was removed through a transperitoneal approach. The patient's condition remained good after operative shock and the patient's condition remained good

reculation had recovered completely after two hours—i.e., four hours after the blockage—and full use of the legs was regained. His renal condition did not improve and he developed a subacute bacterial endocarditis, but he was lost sight of at the time of the second hospital evacuation in Sept., 1939.

Case 5.—Woman aged 36, admitted April 12, 1939, with auricular fibrillation and slight cardiac failure. She was given small doses of gitalin, and on May 5 developed a right femoral occlusion with the typical signs and slight pain. She was operated on within four hours under spinal anaesthesia, and an embolus together with 8 in. thrombus was removed. The circulation recovered perfectly and dilatation of the posterior tibial artery at the ankle could be felt after few hours. She left hospital, and although still fibrillating was doing most of her housework one year later.

I wish to thank Dr. J. Dick, medical superintendent, St. James's Hospital, Leeds, at which hospital I was working, for permission to publish these cases.

GLOBIN-ZINC-INSULIN: SOME EXPERIMENTS

BY

R. D. LAWRENCE, M.D., F.R.C.P.

(From the Diabetic Department, King's College Hospital)

he above new delayed-action insulin—a compound of ox globin, insulin, and a trace of zinc—is already on the market in America, where several articles (see Bibliography) have been published on its action on animals and use in diabetics. These reports seem to have been thought so favourable by the British manufacturers and authorities that I gather it is already licensed and may soon appear for sale. It has received no proper clinical trial in this country (not easy in wartime); but even were it proved to be more useful than protamine-zinc-insulin, seems doubtful wisdom to introduce another new type of epot insulin without withdrawing the old, as this is sure to confuse clinical practice. Moreover, any real new merit in lobin insulin is not apparent to me either from the published works or from the following trials of a supply kindly provided by the courtesy of Burroughs Wellcome and Co.

It is generally agreed that soluble insulin is strong but too short-lived in action, and P.Z.I. weak but prolonged and apt to cause serious hypoglycaemia at night if too large doses are given in an attempt to stop glycosuria after meals. It is hoped that G.Z.I. will be intermediate in action and, with one injection before breakfast, will act strongly and control sugar by day,

lished shows many irregularities and contradictions, and, when one discounts the bias in favour of something new, little real difference. I have substituted 20 to 40 units of G.Z.I. for P.Z.I. in 6 mild cases under hospital control, and my colleague Dr. Wilfrid Oakley has tried other cases, without being able to appreciate any difference on blood and urine tests. I have not compared a series of severe cases in this way, as the results from day to day on any depot insulin are so irregular as to make such a study valueless. But the accompanying table shows the results of what is probably the least erroneous clinical method—the effect of equal doses of different insulins on the fasting blood sugar of a severe diabetic followed for 24 hours without carbohydrate food.

A diabetic man aged 35, on insulin five years, feeble-minded but otherwise organically normal, was the subject. His insulin had varied from 40 to 50 units a day, and was kept at 20 and 16 units during the experimental period. Once a week the evening dose was omitted so that the patient was thoroughly diabetic next morning, and after two fasting blood-sugar estimations at 7 and 8 a.m. (a wise precaution) the same test dose, 32 units, of the different insulins was given. The effect on the blood and urine was followed two-hourly, later three-hourly, for 24 hours, during which time no carbohydrate food was given, but some protein—meat, bacon, etc.—was allowed, which I always find does not affect the blood sugar although it probably increases ketosis. The table shows the blood-sugar results and the ketonuria by Rothera's test—more informative than the glycosuria, which ran strictly parallel. The fasting blood sugars are at a fairly uniform level and the comparisons on the whole satisfactory, although some tests (the blood sugars mostly in duplicate) were lost. Perhaps the contrast would have been clearer with a larger test dose; but any risk of hypoglycaemia had to be avoided, as quite small restorative doses of sugar may raise the blood sugar considerably in such protamine experiments and completely spoil the curves.

It is clear that soluble insulin is much the most active, that neither G.Z.I. nor P.Z.I. gives any very active liberation of insulin during the 24 hours, and that there is no practical difference between the general trend of their action. G.Z.I. seems to come into action more quickly (4 to 6 hours after injection), but its maximum effect is shown at 15 to 18 hours—no different from P.Z.I., and still making the night the most likely time of hypoglycaemia.

There are other points against the present introduction of globin insulin which are more obvious from the clinical than from the laboratory angle. It is clear that its action is weak and that it will have to be supplemented, like P.Z.I., in many cases with soluble insulin. At present a large number of cases are treated with a mixed injection of P.Z.I. and soluble insulin, and we know that some of the soluble is converted by the excess of protamine. We do not know if G.Z.I. contains an excess of globin nor what is the result of mixing G.Z.I. and soluble; but this is of great practical importance, and now is the stage when the initial mistake made with P.Z.I. might be

especially in the afternoon, but will tail off and avoid hypoglycaemia at night, though retaining enough action to prevent a serious diabetic relapse before breakfast—a worthy ambition but a tall order for any one preparation. On the whole the publications and opinions expressed in America suggest that G.Z.I. has more action in lowering blood sugar from 4 to 12 hours after injection and less from 12 to 24 hours than P.Z.I. But a close study of the few detailed protocols pub-

avoided. The manufacturers must know the problem of mixed injections, because I have urged them for years to try to produce a P.Z.I. without an excess of protamine (I gather it contains twice as much protamine as is necessary to precipitate the insulin) so that varying mixtures of P.Z.I. and soluble could be injected with more predictable results. Again, the fact that P.Z.I. is cloudy and soluble insulin clear is a great safeguard against mistakes between delayed-action and quick-

acting insulins; but the new G.Z.I. is a water-clear solution—to my mind, a serious disadvantage. Mistakes between insulins are all too common at present, and I foresee far more if another depot insulin appears on the market, especially if indistinguishable from soluble except for its label. It is difficult for me to understand how a new preparation of such a potent drug as insulin can reach the stage of marketing without serious trial by, and consultation with, the clinicians who will use it. If there is no administrative mechanism for judging and controlling the marketing of new products by their value in practical treatment it ought to be created.

FAUCIAL AND LABIAL DIPHTHERIA

BY

MANUEL ANDERSON, M.D.

Resident Medical Officer, Sheriff Hill Isolation Hospital, Gateshead

Diphtheritic membrane is rarely observed externally on the lip, and the following case, which presents this unusual feature, is deemed worthy of record.

A girl aged 10 was admitted to hospital on Dec. 23, 1942. On the morning of Dec. 21 she had complained of a sore throat and malaise. During the evening of the same day, while chewing a piece of toffee, she inadvertently bit her lower lip. She had no recollection of her lip bleeding. On the morning of the 22nd Dr. Jamieson—her family doctor—was called in. Finding clinical evidence of faucial diphtheria, he took a throat swab, which was reported K.L.B.—

positive next day, when she was sent to hospital. At the time of this examination Dr. Jamieson saw no evidence of labial membrane.

On admission the girl, who was rather undernourished and pale, was moderately ill. There were flea-bites and a few septic spots over her limbs and trunk. Immediately to the left of the midline on her lower lip was a patch of diphtheritic membrane. On eversion of the lip this appeared to be mainly on the upper and internal surfaces. It was quite discrete, oval in shape, and measured about 3/4 in. by 1/2 in. The membrane had a faint yellowish tinge and glistened. It was

thicker in the middle than at the edges. There was a moderate amount of oedema of the lip, with marked injection of the area (see photograph). The tonsils were moderately enlarged and inflamed. Covering the right tonsil was a patch of membrane about 1/2 in. in diameter and a smaller patch was seen on the left tonsil. There was no appreciable fever, and only moderate bilateral cervical lymphadenitis. An enlarged, slightly tender lymph gland was present in the submental triangle. Examination of the circulatory, respiratory, and central nervous systems revealed nothing abnormal. The left knee joint was the seat of long-standing tuberculous disease.

Treatment.—50,000 units of diphtheria antitoxin were administered intramuscularly after a serum-sensitivity test which proved negative. Swabs were taken from both lip and throat; from each of these was isolated "gravis" type diphtheria bacilli. The accompanying photograph was taken shortly after her admission to hospital.

Subsequent Progress.—The day following admission the membrane seemed rather thicker, while the edges began to curl away from the lip surface, so that it appeared even more discrete than previously. After this the process of separation continued by a gradual thinning of the membrane as if its surface were being slowly rubbed away and at the same time by the separation of tiny flakes from the edges, so that the membrane appeared to shrink in extent and thickness simultaneously. That portion of the lip exposed after separation of the membrane was almost "red-raw," and at times a little blood oozed from the surface.

By Dec. 27 separation of faucial membrane was complete, but the labial membrane was still present, although only half its original size. On the 28th a small thin flake of membrane remained on the lower lip, and only slight local oedema was present. On the 31st there was no appreciable diminution in the size of this flake, and it did not disappear entirely until Jan. 2, 1943. The area of the lip exposed showed no evidence of injury after complete separation of the membrane. At this time the only abnormalities revealed on clinical examination were occasional extrasystoles. The patient was allowed up on Jan. 12, and was discharged on the 26th.

Comment

In the literature one can find very little reference to labial membrane, apart from direct extension in cases of late severe faucial diphtheria. An authority of such wide experience as Goodall (1928) says: "The writer has twice seen membrane on the tongue, three times on the lips, twice on the floor of the mouth, and once on the gums." Reiche (1914 (M.R.C., 1923) recorded 49 instances of lesions of the lips among 7,314 fatal cases of diphtheria in Hamburg.

There can be no doubt that in our case the deciding factor was trauma to the lip in the presence of an existing faucial infection. Yet it is evident that, in view of the girl's story, the wound did not bleed; the trauma could only have been slight. It would appear, then, that relatively slight damage to labial mucosa facilitates the inoculation of the bacilli, and it is therefore surprising that labial membrane is not more frequently seen. Carrying the analogy to the fauces, it seems not unreasonable to suppose that Klebs-Löffler bacilli may gain entry to the tonsil epithelium by virtue of minute traumata—possibly as a result of swallowing solid foods. This supposition may be further borne out by the experience that diphtheria is not often seen in tonsillectomized subjects or even in people with very small tonsils, in whom the lack of prominent tonsils would be associated with less possibility of trauma.

Summary

A case of faucial and labial diphtheria is described in which the formation of labial membrane followed slight injury to the lip. The subsequent progress was recorded. It is suggested, from a consideration of this case, that slight trauma to a tissue may readily facilitate the introduction of Klebs-Löffler bacilli.

I would like to express my gratitude to Detective McHugh of the Gateshead Police for the excellent photograph reproduced herewith to the bacteriology department of the City Hospital for Infectious Diseases, Newcastle, for "typing" of the causative organisms; and to Dr. James Grant (medical superintendent of this hospital) for granting me permission to publish this case.

SUCCESSFUL TREATMENT OF A CHRONIC PARATYPHOID CARRIER WITH SULPHAGUANIDINE

BY

H. LOEWENTHAL, M.D., Ph.D.
Pathologist, E.M.S.

AND

W. F. CORFIELD, M.D., D.P.H.
Medical Officer of Health for Colchester

It is generally recognized that human beings are the only source of the causative organisms of the enteric fever group and that carriers play an important part in spreading these diseases. One would probably be justified in saying that most of the outbreaks of paratyphoid fever in this country during the last few years had their origin in carriers. Medical treatment of the carrier condition has been found of no avail, and nothing had arisen up to the outbreak of war to alter the conclusion reached by Browning (1933) and his colleagues that cholecystectomy or other surgical measures directed towards the gall-bladder alone hold any respect of cure.

While sulphanilamide itself and its earlier derivatives had been found to have little therapeutic action on intestinal infections, the introduction by Marshall and his collaborators (1940) of sulphaguanidine with its high bacteriostatic activity and low absorption from the intestinal tract seemed to offer good chemotherapeutic possibilities. Very soon favourable results were reported in the treatment of bacillary dysentery, and it was the favourable impression one of us (H. L.) gained in the treatment of some minor outbreaks of Sonne dysentery that induced us to try its drug in a paratyphoid carrier in spite of the fact that sulphaguanidine had failed to cure dysentery carriers. The paratyphoid carrier, whose cure had been reported by Levi and Allen (1941) was not a chronic carrier, and it is impossible to say whether sulphaguanidine played any part in it.

Case Record

Our patient, Mrs. F., aged 24, a wartime nurse in the E.M.S., contracted the disease while nursing a case of paratyphoid fever in the febrile period of the disease, which lasted for rather more than a month, started on Sept. 3, 1941. She made an uneventful recovery, it continued to excrete *Bact. paratyphosum* B in the stools. Cholecystectomy was performed on Jan. 2, 1942, but the result of this surgical intervention was disappointing, for the carrier state continued unabated.

In July, 1942, Mrs. F. moved into the area served by this laboratory, and after an examination of her faeces had shown profuse growth of *Bact. paratyphosum* B it was decided to try treatment with sulphaguanidine. The first course, which was begun on Aug. 3, consisted of 1.5 g. three times a day for three days, followed by 1.5 g. twice a day for two days—19.5 g. in all; the patient was ambulatory during treatment. It might be mentioned that owing to a misunderstanding the amount of sulphaguanidine received by the patient in the first course was only half that intended.

Several bacteriological examinations from Aug. 10 onwards proved entirely negative for paratyphoid bacilli until Aug. 27, when they started to reappear. At first their number was small and growth could be obtained only after enrichment in tetrathionate broth; but they gradually became more numerous, until finally *Bact. paratyphosum* B was again the prevailing organism on MacConkey and selenite-F agar plates sown directly with the faeces.

Though the result of this first attempt fell short of our expectations, the temporary disappearance of the infective organism, which had not previously been observed in this carrier, was so striking that we could only attribute it to the administration of the drug. Hoping that continued treatment might exercise a cumulative effect, the patient underwent a further course of sulphaguanidine treatment, which began on Sept. 22. On this occasion the patient, whose weight was approximately 9 st., received 50 g. in seven days. This time complete suppression of the paratyphoid bacilli did not occur, but their number was greatly reduced. A third course was started on Nov. 24, the same dose again being given.

Though all subsequent examinations proved negative for paratyphoid bacilli the patient was given a similar and final course in Jan., 1943. *Bact. paratyphosum* B was never again recovered in

six further examinations (Jan. 14, Feb. 2, 16, March 5, April 9, and May 8), and the patient has been clear now for about six months.

Discussion

Can her carrier condition be considered cured? It is a well-known fact that carriers sometimes cease to excrete the infective organisms for periods of several months, and the failure to recover *Bact. paratyphosum* B from this patient's stools for six months would not by itself justify the conclusion that she has been cured. But we have been fortunate in having the collaboration of Dr. A. Felix of the Emergency Public Health Laboratory Service, whose investigations offer strong evidence of the cure of our patient's carrier state.

According to recent unpublished work by Felix a Vi agglutination test, similar to that employed in the examination of chronic typhoid carriers (Felix, 1938), is often an aid to the detection of chronic carriers of *Bact. paratyphosum* B. A steady or rising B Vi titre is suggestive of a probable chronic carrier state, whereas a decreasing B Vi titre in a carrier would indicate that the carrier state was only temporary. With Dr. Felix's consent we reproduce his findings and conclusions:

"The following readings were obtained in the various agglutination tests:

	9/9/42	15/3/43
<i>B. paratyphosum</i> B Vi ..	1:40 ±	1:20 ±
" O ..	1:200 ±	1:100 ±
" H sp. ..	1:200 ±	1:100 ±
<i>Salmonella</i> H group ..	1:100 ±	1:50 ±

"I think that this result indicates that Mrs. F. no longer harbours paratyphoid B bacilli—that is to say, her carrier condition has been cured."

In the summer of 1942, when we decided to give sulphaguanidine a trial in the treatment of our paratyphoid carrier, the recent American literature on the subject was not available in this country. Had we seen it, it is unlikely that we would have tried sulphaguanidine, as the result of a number of well-conducted trials in enteric carriers (Cutting and Robson, 1942; Watt and Peterson, 1942; Saphir, Baer, and Plotke, 1942) had been unconvincing. Those reported successes were restricted to a very few cases, and either the patients treated were not chronic carriers or the data published were not sufficient to allow of a decision on this important point (Hoagland, 1942). We know now also, from personal communications, that previous trials in this country were no more successful.

Before we try to find an explanation for the discrepancy between our own experience and the recent American findings we have to consider the effect of cholecystectomy on the carrier condition. It is known that the infective organisms can persist in the faeces for weeks or even months after the removal of the gall-bladder (Browning, 1933). Though there seems to be general agreement that the onset of the beneficial effect of this operation is not usually delayed beyond three months, Browning (1933) describes the case of a paratyphoid carrier who continued to excrete the specific bacilli for a period of 14 months after cholecystectomy before finally ceasing. Thus, in order to assess the part of sulphaguanidine treatment in the cure of our carrier we have to keep in mind that this occurred approximately nine months after cholecystectomy. But we think we have better evidence for the efficacy of the drug in our case.

As described above, the drug had an immediate and striking effect on the number of *Bact. paratyphosum* B excreted. It would seem unreasonable to suppose that this disappearance of the infective organism from the stools, which had never before been observed in this patient, was solely a late effect of cholecystectomy. Furthermore, after the first course of treatment the paratyphoid bacilli reappeared, to become just as numerous as before; only after two additional courses did they disappear definitely. And here our findings are in agreement with those of Cutting and Robson (1942), who also found a diminution and a temporary disappearance of *Bact. paratyphosum* in the faeces of a carrier after a course of sulphaguanidine.

We feel, therefore, that the success in the treatment of our chronic paratyphoid carrier was due to the cumulative effect of repeated courses of sulphaguanidine, and publish this case in the hope that others may succeed in reproducing our experience.

THE ARIBOFLAVINOSIS SYNDROME

It is now four and a half years since Sebrell and Butler¹ first described the facial lesions of a new syndrome associated with ariboflavinosis, or riboflavin deficiency. They described the bilateral transverse fissures in the angles of the mouth (the perlèche of previous writers), the red shiny lips, and the fine scaly, greasy desquamation around the nasolabial folds, said to be characteristic of the condition. Sebrell and Butler produced these manifestations in women in an institution given a diet complete in all respects but lacking riboflavin. When this was administered later the lesions cleared up. The existence of ariboflavinosis was confirmed in China by Hou² and in America by Jolliffe,³ Spies,⁴ and Sydenstricker.⁵ To the appearances described by Sebrell and Butler, Kruse and his colleagues^{6, 7, 8} added a specific type of glossitis and characteristic ocular manifestations. The tongue was described as clean, the papillae flattened and mushroom-shaped, and the colour purplish red or magenta in comparison with the scarlet tongue seen in some pellagrins. The ocular lesion ascribed to riboflavin deficiency was a superficial vascularizing keratitis, characterized on slit-lamp examination by circumcorneal injection, invasion of the cornea by capillaries from the limbic plexus, and superficial corneal opacities, the lesion being manifested subjectively by dimness of vision, photophobia, lacrimation, and burning of the eyes. Later Métivier⁹ described further ocular lesions, which she thought were due to riboflavin deficiency because they responded to treatment with this vitamin. One she calls tropical nutritional amblyopia, which appears to be the nutritional retrobulbar neuritis of other writers, and the other essential corneal epithelial dystrophy. Métivier claims that this is a new eye disease characterized by a faint greyish-white disturbance in the corneal epithelium, made up of fine points like dots and commas, and staining with fluorescein. She also describes a form of conjunctival injection which she calls "rosy eyes," characterized by an apple-pink injection of the ocular conjunctiva exposed in the intrapalpebral area.

Later investigations have shown that certain of the manifestations originally stated to occur in the ariboflavinosis syndrome are not always associated with riboflavin deficiency; at all events they do not invariably respond to treatment with riboflavin. Thus cheilosis may occur independently of ariboflavinosis. Ill-fitting dentures, resulting malocclusion, have been reported by Ellenberg and Black¹⁰ as a factor in its causation. The cases described by these authors failed to clear up when given riboflavin, but did so when the malocclusion was corrected. This observation appears to be valid and has been reported by others.¹¹ Cheilosis has been observed in a case of post-encephalitic Parkinsonism receiving a normal diet; the salivation may have been responsible here. There is also some evidence that cheilosis may be associated with such diverse conditions as hypochromic anaemia¹² and sensitivity to lipstick and chewing-gum. Machella and McDonald¹³ have failed to cure a number of cases of cheilosis with riboflavin. Some responded to nicotinic acid, pyridoxine, and the entire vitamin B complex. There are cases which resist vitamin therapy of any type. Some

of the other lesions attributed to riboflavin deficiency are also apparently non-specific. Thus Smith¹⁴ states that the seborrhoeic facial lesions described by Sebrell and Butler do not yield to riboflavin therapy, but respond to nicotinic acid slowly and to yeast rapidly. Machella and McDonald¹⁵ have also failed to improve patients with the tongue lesions said to be characteristic of ariboflavinosis by administering riboflavin, though pyridoxine and yeast were curative in some cases. The corneal vascularization described by Kruse and his colleagues,^{6, 7} and employed by him in survey work as pathognomonic of ariboflavinosis,¹⁵ has been shown by Sandstead¹⁶ to be quite non-specific and present in from 80% to 95% of children, youths, and adults examined, and without any other signs of ariboflavinosis. Sydenstricker and Kruse⁷ also described circumcorneal injection as an early sign of ariboflavinosis, but Scarborough¹⁷ has shown that this is also non-specific, because it occurred in some 30% of unselected hospital out-patients seen by him and with no other signs or history of ariboflavinosis. Boehrer and his co-workers¹⁸ placed three volunteers on a diet low in riboflavin (0.471 mg. daily) but adequate in other essentials, and failed to observe any signs of corneal vascularization after five weeks. Yet this appeared in a control subject receiving 3.5 mg. of riboflavin daily. The vascularization persisted even after three weeks on a "normal" diet and a further fortnight's treatment with 9 mg. of riboflavin daily.

Our conception of ariboflavinosis may need considerable modification when the results of investigations being carried out in this country and America are known. Experimental studies indicate that there is an individual variation in the requirement of riboflavin, independent of body weight and other known factors. Lack of balance in a diet may also produce manifestations of ariboflavinosis even on a high intake. Some other factor or factors may also be essential for the proper utilization of riboflavin. Thus Spies and his co-workers¹⁹ have emphasized the roles of pyridoxine and pantothenic acid in its mobilization and utilization. It may be that a deficiency of other factors of the vitamin B complex, such as choline, inositol, and adenylic acid, complicates the so-called ariboflavinosis syndrome. It must also be borne in mind that the staple diet of the cases described in America was maize; in this country, where ariboflavinosis is rarely described, it is wheat. Does deficiency of an essential amino-acid play a part? These problems await solution.

NERVOUS SHOCK

That powerful emotions are associated with physiological changes and widespread bodily sensations is a commonplace. That these, though ordinarily transient and trivial, may be lasting and severe is a phenomenon dimly recognized in popular speech—in such familiar phrases as "he nearly died of fright" or "she fainted for joy." The qualifying adverb is, however, rarely omitted. Historical instances abound, but here the pathology must be interpreted with caution. Scientific support for the fatal effects of emotion is rarely forthcoming. Particular interest therefore attaches to a case reported recently by Stürup.²⁰ A woman of 35 was admitted to the psychiatric clinic in Copenhagen in a state of stupor. There was a history of earlier paranoid symptoms, and, although the diagnosis made was that of a psychogenic paranoid psychosis, the history suggests schizophrenia. She was treated with insulin

without success. Cardiazol was impracticable as the veins were difficult of access. After a few months this drug was given, but without avail. The patient was then still in stupor interrupted by accesses of rage. Five minutes after witnessing a violent outburst of rage by another patient she became short of breath, poured forth a flood of speech, said she had had a "shock," and could not be pacified. She showed the clinical signs of shock, with imperceptible pulse, chilly extremities, and a rising rectal temperature. Six hours later a blood transfusion was attempted, but failed because a vein could not be found in the cubital fossa. The patient was analgesic; no bleeding took place from the severed skin, and even section of the radial artery yielded only one drop of blood. It was impossible even under pressure to inject any fluid into the distal portion of the artery. A later attempt on the femoral vein showed it to be about the thickness of a knitting needle and whitish. Fluid was, however, injected with transitory improvement in the patient's condition; the analgesia disappeared, but 16 hours after the onset of the shock symptoms the patient died. Necropsy revealed much oedema of the lungs with stasis and haemorrhages and scattered bronchopneumonic patches. There were fragmentation of the myocardium, stasis in the kidneys and liver, and evidence of cerebral oedema but no stasis in the cerebral vessels.

Stürup discusses earlier work of his concerning the effect of painful stimuli on limb volume. He reached the conclusion that such stimuli induced peripheral vasoconstriction by creating a state of increased alertness to danger, and explained the subsidence of the reaction noted on repetition of the stimulus as due to loss of its "alarm character." He thinks this state may be the nervous precursor of Cannon's "emergency reaction," which appears when real danger threatens. He believes it justifiable on the basis of this work to assume a similar mechanism in the patient described, terror leading to peripheral vasoconstriction with diminished loss of heat and hence raised internal temperature. He alludes to the febrile episodes in psychotics which occur notably after hallucinations of strongly anxious character, and stresses the initial signs of terror in his patient. He has observed similar states in puerperal confusions, and mentions the value of insulin in suitable doses as a life-saving measure in these cases. He believes that several of the cases reported by Scheid some years ago belong to this group. Stürup considers that such states as that described can occur in mentally normal people in response to violent emotions where an over-sensitivity of the vegetative nervous system can be postulated. He also thinks that so-called "surgical shock" may arise in a similar way in cases in which fear and loss of blood have produced the necessary sensitivity of the vegetative nervous system, and indicates the necessity for prompt treatment. Be that as it may, such states of "shock" are by no means uncommon in schizophrenics, and for this an adequate explanation is still awaited. It might also be expected that in these days such states as Stürup describes would be seen with some frequency, but so far they do not appear to have been recorded.

TREATMENT OF EYES INJURED BY MUSTARD GAS

We are indebted to Mr. A. F. MacCallan for recalling that in Sept., 1918, at a French military hospital in France Dr. G. Bonnefon,¹ the only ophthalmic surgeon there, without medical assistance and without specially trained medical orderlies, had to treat 1,800 men in whom both eyes had been affected during a mustard-gas attack. These were

treated at the rate of 200 eyes an hour according to the method to be described and contrary to the official instructions of the Service de Santé. The principle of the treatment consists in osmotic drainage of the affected mucous membrane by means of an eye-bath filled with hypertonic solution.

The clinical picture of the eye injured by mustard gas has three distinct phases: phase of impregnation, acute phase, and phase of recovery. The phase of onset is without symptoms, the eye exposed to blister gas allowing itself to become impregnated without manifesting any pain or discomfort. This lasts from one to three hours. The acute phase begins suddenly with hypersecretion of the conjunctival and lacrimal glands. Stabbing pain accompanied by photophobia begins, and in a few minutes the clinical picture is completed by such oedema of the eyelids as to close the palpebral fissure. The eye is now almost exactly like that of an infant with gonococcal ophthalmia neonatorum, except that there is no purulent discharge. When it is possible to open the palpebral fissure a yellowish blistering fluid spurts out. This phase lasts from two to five days, but may be shortened by judicious treatment. The phase of recovery is characterized by a progressive diminution of the palpebral oedema, but the lacrimal secretion and photophobia persist, with marked dilatation of the submucous capillary network. This phase may last for weeks or months in severe cases. Sometimes secondary infections of the conjunctiva or cornea occur, but these have no direct relation to the blistering action of the gas, which has long disappeared. Further skilled treatment by an ophthalmic surgeon may shorten or prevent this phase of sequelae.

The mildness of the ocular lesions caused by blistering gases as compared with their destructive effect on other parts of the body is indisputable. In contact with the tissues mustard gas (dichlorethyl sulphide) undergoes hydration with formation of hydrochloric acid. Severe pain is experienced and the defensive mechanism of the body is brought into play. No organ is more exposed or better protected than the eye. There are the reflex flow of tears, which clears away the acid from the conjunctival fornices and from the ducts of the meibomian glands: osmotic action, which fills up the subepithelial lymph spaces: dialysis of fluid from the submucous capillaries. This superficial and deep lavage prevents any eruption of blisters. In 1917 Bonnefon saw, in the narrow valley of Belrupt near Verdun, a battery of horse artillery which had been shelled with mustard gas the day before. A number of the horses exhibited absolutely opaque corneae as a result of the gas, while none of the gunners had to be sent to hospital, though some of them had not been wearing their masks. He observes that the horse and the rabbit have no lacrimal secretion or periorcular lymphatic defences which in man render the eyes less liable to damage by gas. It is therefore reasonable to conclude that, since the natural defences of the ocular adnexa suffice to protect human eyes when slightly damaged by gas, in severe cases the aim should be to reinforce the natural mechanism. Bonnefon carried this out after another heavier gas attack, as soon as the casualties arrived at the first-aid post, by cleaning up the eyelashes and applying an eye-bath filled with a warm hypertonic lotion. This consisted of saturated solution of sodium sulphate 800 grammes (about 1½ pints) and syrupus simplex 200 grammes (about 1/3 pint). However great may be the palpebral oedema, this solution enters the palpebral fissure and penetrates to the fornices and osmotic drainage occurs. After ten minutes of immersion the fluid in the eye-bath becomes acid, proving the efficacy of the treatment. With 200 eye-baths and four first-aid assistants, 1,500 eyes were bathed twice a day. This osmotic treatment should be continued not only during

¹ "L'Œil syphilité: Son Traitement." *Gaz. hebdomadaire de Sci. Méd.*, 1939, 60, 168, 179.

the acute stage, but also so long as there is any photophobia and lacrimation. When an analgesic is needed Bonnefon recommends the instillation of a 2% solution of dionine (ethyl morphine).

The treatment for gassed eye given in the official *Medical Manual of Chemical Warfare*, 1943, pp. 16 and 19, envisages the flushing of the conjunctival sac with water if this can be done within five minutes, the instillation of atropine as a mydriatic and of albucid soluble 2.5% as an antiseptic. If the discharge is excessive the conjunctival sac may be washed out with normal saline solution twice a day. Cocaine must never be used as an analgesic as it will cause damage to the corneal epithelium. Liquid paraffin and oily drops must never be used while there is a possibility of any dichlorethyl sulphide remaining in the conjunctival sac, because they are solvents thereof and further damage may be done. Mr. MacCallan's criticism of this treatment is that if atropine is used as a routine for slight casualties the recipient will be out of action for a week or longer, while in a case of only moderate severity one cannot introduce a satisfactory amount of irrigation fluid into the conjunctival sac on account of the tight closure of the lids.

ALCOHOL AND THE BRAIN

From the dawn of history man has used the depressant action of alcohol on the cerebral cortex and its effect in releasing the lower centres as an aid to conviviality in social intercourse, and as an escape from the tension and drabness of his everyday life. Alcohol depresses those parts of the brain the functions of which are chiefly inhibitory, so that the power of restraining the emotions is impaired. What happens to the alcohol that has loosened the tongue of the after-dinner speaker or has produced oblivion in the habitual toper? Little is known of the way in which it disappears from the brain. It was always thought to be metabolized in the tissues and not in the central nervous system, which was supposed to metabolize carbohydrate only. Enough evidence has now accumulated to show that alcohol is oxidized by the cells of the central nervous system. Alcoholized brain tissue takes up more oxygen than normally respiring brain tissue,¹ and as the respiratory quotient of the tissue shifts towards that of alcohol it may be assumed that the increased oxygen consumption is concerned with the metabolism of the alcohol.² However, in acute alcoholism there is a diminution in the cerebral oxygen consumption, due to the depressant action of large quantities of the drug.³ The presence of an alcohol-oxidizing enzyme system in the brain of several species has now been demonstrated by Dewan⁴ of Ontario, and it may be assumed that a similar mechanism exists in the brain of man. Two members of the vitamin B complex—namely, nicotinic acid and riboflavin—are components of this system. As this catalyses the consumption of alcohol in the brain, and as alcohol is known to depress the functioning of the latter, Dewan suggests that this enzyme system probably acts as a detoxicating or protective device after excessive alcoholic indulgence. It is well known that alcoholics eat sparingly and suffer from vitamin deficiencies, particularly of the vitamin B complex. Owing to the relative deficiency of nicotinic acid and riboflavin in such persons alcohol may reach a high concentration and remain for a long period unmetabolized in their central nervous system. It would therefore appear essential to increase the intake of nicotinic acid and riboflavin not only in the chronic alcoholic but also in the heavy drinker,

to ensure efficient removal of alcohol from system. As Dewan points out, the fact that equipped to metabolize alcohol indicates that nervous system is more versatile chemical thought.

PLANNING OF ACCIDENT SERVICES

Fractures may be the most important of the countered in accident departments, and the variations for rehabilitation coming forward in have had fractures chiefly in view. But an a vice must also embrace the treatment of injury tissue, infections of the hand, burns, tendon injuries, and indeed all injuries of the locomotor many of which are no less incapacitating than and in total outnumber fractures in the proportion of ten to one. This point of view is urged in a memorandum on accident services published by the British Orthopaedic Association. It is pointed out that many hospitals now have special fracture departments, but special accident departments, always excepting developments as those at Birmingham and Oxford, have not. Great attention has been given to the organization of accident services. "Too often," says the memorandum, "the most junior resident is given the responsibility of wounds, lacerations, and soft-tissue injuries, unaided by senior members of the visiting staff. The planning of casualty departments to meet the needs of accident services is suggested. Near the entrance to the accident department many cubicles should be provided where patients can be prepared, examined, and treated in case of shock. There must be immediate access to the radiology department and from this to emergency theatre. Hospital beds must be available so that "minor" injuries can be treated under ideal conditions. In every department an orderly, nurse, or masseuse should concentrate on rehabilitation. Continuity of treatment must be maintained from the phase of emergency operation to in-patient treatment and out-patient supervision and rehabilitation and after-care. The memorandum also suggests that orthopaedic surgery, which is the surgery of the locomotor system and concentrates on function, is not a specialty. It requires men who have been trained in every branch of the subject—"traumatic surgeons" but surgeons experienced in the locomotor system. Suggestions are made for the organization of an accident department of a general hospital, and a point is also made that in rehabilitation there should be groups of cases to be differentiated—namely, those of sedentary and light industrial workers, who can be rehabilitated, as a rule, within the precincts of the hospital, and the injuries of heavy industrial workers who may need special centres in country situations, with provision for residence.

Dr. C. M. Wenyon, F.R.S., will retire shortly from the position of director-in-chief of the Research Institution and director of the Wellcome Scientific Research. He has been associated for over 20 years with the research laboratories founded by the late Sir Walter Wellcome. Dr. Charles H. Kellaway, F.R.S., director of the Walter and Eliza Hall Institute for Medical Research, will take over the directorship-in-chief of the Wellcome Foundation's other research laboratories as far as possible. Dr. Wenyon has agreed to postpone his departure until Dr. Kellaway reaches this country. Dr. N. Fairley, F.R.S., now serving with the rank of Colonel as director of medicine to the Australian Army in London, will eventually take over the directorship of the

MILK AND ITS PROBLEMS

A NUTRITION SOCIETY DISCUSSION

For the second time the Nutrition Society has held a joint meeting with the Food Group of the Society of Chemical Industry—this time on "milk," under the chairmanship of Prof. H. D. KAY, Director of the National Institute for Research in Dairying. Dr. Kay reminded the audience that the future of both nutrition and farming in Britain was bound up with the supply of milk, a key foodstuff. Special wartime problems of milk supply had interested three separate Ministries, and it was desirable that this collaboration should continue into the post-war years. A regular 10% yearly increase in the consumption of milk could then be hoped for, although it was necessary to remember the effect of the steadily changing age distribution of our population on any future expansion. Dr. Kay also insisted on the importance of adequate training of technical personnel engaged in milk production and distribution, and he welcomed the recent formation of the Society of Dairy Technologists.

Some Facts about Dairy Production

Mr. J. L. DAVIES, an officer of the Milk Marketing Board, gave an important factual survey of dairy production in this country. When his paper appears in full in the *Proceedings of the Nutrition Society* it will be interesting to study the figures of the distribution of farm sizes and herd sizes in Great Britain, and the number of producer-retailers in the country. Mr. Davies concludes that about half the farmers in the country are concerned in milk production, and that efficiency is possible with herds of from 15 to 100, provided conditions are suitably adjusted. He pointed out certain pitfalls in finding a true "average" figure for the annual milk yield of cows in this country; in his view it was legitimate to aim at a figure of from 600 to 650 gallons under good dairy-farming conditions. He made it clear, however, that these are often far from proper, and like other speakers he deplored the drudgery experienced by operatives working in bad conditions, and insisted on the importance of securing for dairy-farm workers at worst a six-day week and equipment enabling them to put into practice the universally accepted views of nutritionists and other health authorities. In Mr. Davies's view, half the dairy-farms in the country need extensive improvements, and one-third need complete rebuilding; the capital cost of such changes would be about £100 million. If plans are made now, it should be possible to secure the changes within ten years of the end of the war. A ten-year plan would also be needed to eliminate disease from our herds. If all the necessary steps were taken we could expect to produce enough milk to allow for an average daily consumption of at least three-quarters of a pint; in May of this year it actually reached the figure of 0.65 pint, compared with 0.37 just before the war. It is impossible here to do justice to the value and extent of the detailed figures supplied by Mr. Davies.

Pasteurization: Milk Nutrients

Dr. A. T. R. MATTICK of the National Institute for Research in Dairying read a paper in which many technical aspects of pasteurization were considered—including both the holder and the high-temperature-short-time (H.T.S.T.) methods. He spoke of the importance of pasteurization for stock feeding, as well as for the production of liquid milk intended to be drunk by human beings. Besides describing different methods of heat sterilization and the effects of these on various types of organism likely to be present in milk, whether from the infected udder, the farm-hand, the dairy water-supply, or the atmosphere to which the milk is afterwards exposed, Dr. Mattick condemned the view that "any old milk" could be pasteurized. Two of the practical proposals made by him are: first, an official ban on feeding farm animals with infected milk, and, secondly, the legal enforcement of a pre-pasteurization maximum bacterial count, if only in the interests of the producers themselves. Dr. Mattick also called attention to the importance of plant design management in the post-pasteurization handling of milk, particularly the bottling stage.

Dr. S. K. KON, also of the Institute, led a whirlwind tour through the land of milk nutrients, illustrated by some admirably summarized tables and diagrams. Speaking as a

nutritionist, he gave most of his figures in terms of 1 pint of milk as the desirable daily consumption, thereby confirming the urgent plea of Mr. A. L. Bacharach, during the later discussion, that we should certainly not accept Mr. Davies's modest three-quarters of a pint as the ultimate goal of dietary sufficiency. Dr. Kon emphasized the importance of milk protein, not only because of its own high biological value but because of its supplementary effect on the cereal proteins with which it was habitually consumed. The traditional combination of bread and cheese is justified by amino-acid analysis. Dr. Kon also emphasized—an emphasis unfortunately more necessary to those absent from the meeting than to those present—that the effect of pasteurization, drying, condensing, and evaporating on the nutritive value of milk is negligible and of no consequence compared with the enhanced safety given by such processing. Dr. Kon made the point that separated milk, liquid or dried, is for adolescents and adults almost every bit as valuable as full-cream milk. In particular the supplementary value of milk protein applies to separated as much as to whole milk.

The figures given by Dr. Kon made it clear that the various nutrients in milk show a considerable range. He stated the problem—reiterated by the chairman in his closing remarks—of turning from considerations solely of quantitative milk production to nutritive value. It should be possible both to feed and to breed with the object of producing cows that will yield milk having not only constant but maximal amounts of its essential nutrients. During the discussion Prof. A. W. ASHBY expressed scepticism about figures that had been put forward to illustrate the extent to which this loss could be avoided. Prof. Ashby's views were obviously not accepted by Dr. W. R. Wooldridge.

Pasteurization Again

Some of those present thought that Prof. G. S. WILSON painted too black a picture of the present milk position. But there was no pessimism about his view that almost if not entirely all the present troubles arising from the distribution of unsafe milk could be most expeditiously and safely met by compulsory pasteurization. He devoted a little consideration to the "arguments," as they are sometimes called, of those who oppose pasteurization in general, and compulsory pasteurization in particular. There is, for instance, the tragic idea that immunity can be purchased by the hit-and-miss method of distributing tuberculous milk unsystematically, and at the cost of 1,500 to 2,000 young lives annually. One speaker suggested that those using this argument should be invited, on the basis of their own advocacy, to insist that all milk should be injected with a small immunizing dose of live tubercle bacilli. Prof. Wilson said that pasteurization was needed not only for the elimination of the bovine tubercle bacillus but also for eradicating *Brucella abortus* infection, post-secretory contamination from carriers of diphtheria bacilli, haemolytic streptococcus, and other pathogens.

In conclusion Prof. KAY stressed the connexion between a healthy food policy and a healthy agriculture in Britain, and insisted that pasteurization of raw milk supplies was a condition precedent to the nutritionally desirable increase of milk supply and consumption that had been so much in the foreground in the day's discussion. He also urged that research and practice should concentrate on reducing the variability of milk, and that we should aim at a standard of nutritive value below which it should be illegal to sell milk for consumption.

ALLOCATION OF MEDICAL MAN-POWER IN
NORTHERN IRELAND

On Jan. 12, 1942, the Minister of Home Affairs appointed a Medical Personnel (Priority) Committee to consider the most economical allocation of the available medical manpower in Northern Ireland and to promote measures for securing the maximum co-operation to meet civil and Service needs in the area and the elimination of overlapping. This committee has since presented two interim reports, the main conclusions of which and the action taken on them being as follows:

(a) Figures supplied by the Central Medical War Committee show that of the total number of doctors whose names appear

in the Northern Ireland Section of the National Register of Members 20.6% are now serving with H.M. Forces. This figure is largely due to the good response which has been made by recent graduates; of the men who have qualified since 1938 60% have joined the Forces, the highest percentage in any one year being 72; and, if women graduates are included, the respective figures are 53 and 66. These figures, though relating to a system of purely voluntary enlistment, are nevertheless reasonably close to those applicable to the rest of the United Kingdom. It should also be borne in mind that a substantial number of Northern Ireland medical men have been recruited into the Forces elsewhere than in Northern Ireland.

(b) That the right of entry into panel practice should be restricted during the emergency with a view to protecting the practices of doctors in the Forces and to encouraging others to join. The Ministry of Labour has given effect to this recommendation by a Regulation made under the Emergency Powers.

(c) If conscription were to be applied to the medical profession in Northern Ireland it is unlikely that any further contribution would be possible from amongst the consultants and specialists, doctors holding hospital appointments, or those engaged in the public health, teaching, or research services.

(d) A substantial contribution would, however, be called for from among general practitioners. In the opinion of the committee it would be possible to maintain an efficient medical service for the civilian population under war conditions and at the same time to release for service in H.M. Forces a considerable number of doctors now engaging in private practice as principals (probably about fifty), and also a small number of assistants. The committee realizes the practical difficulties in the way of achieving this result on a voluntary basis.

Reports of Societies

INJURIES OF THE SPINAL CORD

At a recent meeting at Glasgow of the British Orthopaedic Association, under the presidency of Mr. G. R. GIRDLESTONE, there was a discussion on injuries of the spinal cord.

Mr. R. C. MURRAY, in an analysis of 21 patients admitted to an E.M.S. hospital, stated that the neurological lesion could usually be accounted for by a study of the radiographs, but that where no adequate cause was shown there might be a protrusion of bone from the back of the vertebral body which must be considered as a possible indication for early laminectomy. His series supported the view that in cord lesions with complete loss of function lasting 24 hours no recovery could be expected in segments below the lesion. Recovery was most possible in cervical lesions and in those below the first lumbar vertebra. There was no limit to the time of recovery of motor fibres in the roots and cauda equina. Reduction should be carried out in all cases, for even in complete cord lesions this might lead to the recovery of some roots and add two or even three useful segments. Reduction should be followed by fixation; in the cervical region by continuous skeletal traction; after operative reduction by a hyperextension plaster jacket; and in cauda lesions by a plaster bed and turning case. The greatest difficulty, on account of pressure sores, was in dorsal lesions for which a complete combined plaster jacket and double spica were advised, so as to distribute pressure evenly and also facilitate turning and relieve pain and spasm. For treatment of the bladder tidal drainage was recommended. Finally, few cases should be regarded as hopeless, for even with a complete lesion at the level of the conus a patient might learn to walk.

Mr. ROLAND BARNES, reporting on a similar group of patients, stressed the importance of accurate sensory testing in assessing the degree and the prognosis of the spinal cord injury. It was more valuable, he said, than knowledge of the extent of motor paralysis. He had found that the prognosis was worse in lesions at the level of the twelfth thoracic vertebra than in those of the first lumbar. Laminectomy was never indicated

as an immediate operation, but should be done when there was an incomplete paraplegia not showing spontaneous recovery, if there was evidence of increasing pressure upon the cord, or for severe and intractable root pains. He agreed that reduction of vertebral displacement should always be attempted, particularly if the paraplegia was incomplete. Radiographs of the highest quality were essential. Fracture-dislocations with locked facets were commoner than was generally realized. For this injury an open operation was indicated; the excision of articular processes should be avoided so as to maintain the stability of reduction, which usually should be further assured by internal fixation. For such operative cases he preferred a plaster bed and turning case.

Phosphatase in Bone Diseases

Prof. NOAH MORRIS, in a review of the present state of knowledge of phosphatase in diseases of bone, said that this enzyme, the function of which was to accelerate the conversion of organic into inorganic phosphate, was widely distributed in the tissues. If jaundice was excluded, increase of plasma alkaline phosphatase was pathognomonic of the presence of bone disorder. Of itself, however, it was of little value in the differential diagnosis of osseous lesions, but taken in conjunction with clinical, radiological, and other biochemical findings it was often of considerable assistance. The cause of the increase in plasma phosphatase was of some importance not only theoretically but also from the standpoint of the clinician. Destruction of bone *per se* was not accompanied by any marked increase of plasma phosphatase unless new bone or osteoid tissue was being formed. In the healthy individual the plasma phosphatase increased during periods of growth. Acceleration in rate of growth was associated with increased activity of osteoblasts. The factors regulating osteoblastic activity almost certainly included the rate of deposition of calcium salts. A reasonable hypothesis might be that if ossification was not maintained at a rate sufficient to meet the degree of cellular activity on which phosphatase formation depended, excess of ferment passed over into the plasma. If this hypothesis was correct an increase of plasma phosphatase might be expected as a result of: (a) increase in bone cell activity at such a rate that it could not be satisfied by the available calcium, or (b) insufficient intake of calcium and/or vitamin D.

With Mr. Matthew White he had been able to follow the course of the plasma phosphatase in a child with healed rickets during a period of calcium starvation and ammonium chloride administration. Here with the defective supply of calcium the plasma phosphatase showed considerable increase. The findings of Woodward and his co-workers with primary and metastatic tumours of the bone showed that with primary tumours an increase of plasma phosphatase occurred only when the tumour cells were producing phosphatase at a rate very much higher than that of normal bone tissue, and that a fall of plasma phosphatase after surgical removal or irradiation therapy was due to the withdrawal or inactivation of the phosphatase-forming cells. In bone metastases the increase of plasma phosphatase appeared to be due to a defence reaction manifested as increased bone formation adjacent to the tumour cells. Only when the reaction was osteoplastic did the serum phosphatase increase. In osteolytic lesions little change was observed.

It was clear that in many pathological conditions of bone such as rickets, osteomalacia, Paget's disease, and others, the variations of plasma phosphatase afforded a valuable guide to the course of the disease, the prognosis, and the effect of any therapeutic measure. Acid phosphatase was seen in many tissues, but if an increase was found in the plasma it almost invariably derived from prostatic glandular epithelium. Normally very little prostatic phosphatase appeared in the plasma, and it was abnormally high only when the blood and lymph vessels were invaded by tumour cells derived from the prostate. Of special value were serial determinations of plasma acid phosphatase in assessing the results of castration or oestrogen therapy.

Infection in Burns

In a paper on the control of infection in burns Dr. LEONARD COLEBROOK divided such infections into two groups: (1) the coccal infections of the first week, which were the most threatening to life and to rapid recovery but the control of which was well within sight; (2) the bacillary infection occurring when sloughs were separating, and which were largely responsible for the patient's anaemia and low state. The control of these might be expected only when much more trouble was taken in the prevention of hospital infection—especially from dust—and when a chemotherapeutic agent was available which was as effective against them as penicillin was.

against the cocci. In 310 cases of burns admitted to the special unit of the Royal Infirmary, Glasgow, the methods used to obtain improved results included: strict aseptic precautions during the first few hours following admission, among them the use of sterilized blankets; an attempt to sterilize the burned surface by means of C.T.A.B. solution (without anaesthesia); the application of a bacteriostatic dressing which could be left undisturbed for 7 to 10 days (sulphanilamide or sulphathiazole in lanette wax SX and castor oil base—10% for most cases, 3% for extensive burns); prompt elimination by means of penicillin or propamide of haemolytic streptococci from burns already infected, and various measures for reducing cross-infection—e.g., strict "no-touch" dressing technique; elimination of dust; masks, etc.

Mr. JAMES PATRICK, in a paper on supination and pronation in forearm fractures, stated that when a fracture had been well reduced it was found that limitation of movement was only to be feared in severe fractures of the head of the radius and fractures lower down in either bone which involved the attachment of the interosseous membrane by fibrosis, ossification, or shortening. It was important to realize that the axis of radial rotation was exactly along the interosseous ridge of the ulna. He emphasized the importance of lesions of the triangular fibrocartilage at the inferior radio-ulnar joint, not only in Colles' fracture but also in fractures of the head of the radius. For the latter cases he recommended early active rotation movements after the head had been excised. In fractures of the shafts of the radius and ulna operation should be avoided so far as possible; where necessary only the radius should be exposed and its interosseous aspect should not be encroached upon. Where cross-union occurred in the lower third of the forearm, excision of a segment of the ulna, including the fracture, gave good results. For permanently severe loss of rotation after Colles' fracture excision of the lower inch and the articular portion of the ulna also was good. Late angulation of fractures of both forearm bones was shown to be due to wasting of the brachio-radialis muscle, which allowed sagging of the fracture within the plaster case. Adequate support in the middle of the forearm mitigated this complication.

Other Papers

Mr. I. S. SMILLIE, in a paper on the regeneration of the menisci of the knee-joint in man, described the fibrous structure, which partially replaces an excised meniscus. It was densely adherent to the synovial membrane at its periphery, it was thinner and narrower than the normal structure, and was whiter because it was composed of fibrous tissue only. Five cases were described in which regenerated "cartilages" had been torn—a circumstance which was rare unless factors producing gross instability were present within the joint. Dr. G. W. ARMSTRONG of the Canadian Orthopaedic Unit, with a cinematograph film, described his method of internal fixation by screws in carefully selected cases of oblique fractures of the tibia. Mr. ARTHUR PARKES read a paper upon traumatic ischaemia of peripheral nerves occurring in a group of patients in whom a severe injury to the leg, with or without fracture, had been followed by gross swelling of the limb and anaesthesia of gradual onset spreading centripetally from the great toe over the foot and ankle. Later, objectively, paralysis with the reaction of degeneration was observed in all the intrinsic muscles of the foot with sensory loss in the distribution of all the deep nerves. Recovery was very slow. The condition was thought to be due to tension under the deep fascia from extravasation of blood and tissue fluids, causing ischaemia of the nerve trunks by pressure. For treatment it was suggested that early operation was indicated even when the peripheral pulse was present. Incisions through the deep fascia would relieve tension and prevent the development of an extremely disabling condition.

Clinical demonstrations were given at the Glasgow Royal Infirmary and at the Philliphill Orthopaedic Hospital. At the latter Dr. A. K. BOWMAN, introduced by Mr. JAMES RUSSELL, gave an account of the influence of Glasgow in the development of orthopaedics, particularly in relation to the work of the Hunters, of Lister, and of Macewen.

The British Council has received a report from the Institute of Natural Science in Yenan, N.W. China, that Dr. Arow, a Soviet medical man, seeing the shortage in sources and the high price of cotton-wool, and the great demand for medical cotton-wool in surgical work, collected a great deal of spirogyra from the Yen River, dried it in the sunlight, wrapped it in gauze, disinfected it, and used it as pads to absorb pus and blood. According to practical clinical experiments, the absorbing capacity of spirogyra is five times that of gauze and seven times that of cotton-wool. The doctors in Yenan intend to use it on an extensive scale.

Correspondence

The Diet in Diabetes

SIR.—Dr. G. R. W. LUNTZ (July 3, p. 21) agrees with Prof. R. H. MICKS (May 15, p. 598) in thinking that it is sufficient to treat a diabetic patient with insulin and an unrestricted diet. However, he thinks that this is undesirable for elderly obese patients and says that these should be strictly dieted. I agree with him that this type of patient should be carefully dieted, and that many of them will cease to pass sugar and have a normal blood sugar if the carbohydrate is restricted to about 100 g. carbohydrate. It may be necessary to give insulin as well for a time, though in this type of case it can often be given up. There is another large group, in whom I believe, as does Prof. Micks, that it is possible to control the glycosuria with great benefit to the patient. The great majority of patients of all ages who have an acute onset of diabetes are very easily controlled, whether the diet contains 150 to 250 or even 300 g. of carbohydrate, depending on the age and activities of the patient, together with 60 to 80 g. of protein and 70 to 100 g. of fat per day for an adult. While these patients are being stabilized and while they are improving under treatment they may have mild attacks of hypoglycaemia, but if care is taken these are rarely severe. Under these conditions the dose of insulin will often decrease from, say, 50 units to 20 or 10 units a day, and may in some cases be discontinued altogether for short or long periods. Patients are always pleased when the dose of insulin can be decreased and much prefer taking small doses to large ones; they are also pleased when the urine contains no sugar at all. If a patient fails to improve sufficiently to be able to give up insulin, Prof. Micks allows his patients to have an unrestricted diet. I, on the other hand, having with the help of dietitians trained the patients during this period how to vary their diet so as to make it palatable, find that the great majority of them maintain their diets carefully and vary their own dose of insulin. These patients keep well and lead very active lives.

A few patients are difficult to control from the beginning of the illness and are liable to frequent overdoses: others may develop this tiresome complication after the lapse of from one to nineteen years, and it is especially dangerous when the patient ceases to recognize the symptoms of hypoglycaemia. I agree with Prof. Micks and Dr. Luntz that these patients must be allowed to have a high blood sugar after meals, though this will not prevent all the attacks, as the hyperglycaemia may change so quickly to hypoglycaemia. Some of these patients are then uncomfortable and suffer from thirst and polyuria and lack of energy because the blood sugar is so high, though others do not have any such symptoms. Neither Prof. Micks nor Dr. Luntz gives any idea of the height of the blood sugar of his patients. I wonder whether they would disapprove of a blood sugar of 540 mg. per 100 c.c.m. which I recently found in a girl of 14 who had just been discharged from a clinic which believes in unrestricted diets. She was then taking 76+60 units, but after being in hospital for two weeks on a diet containing 200 g. of carbohydrate with about 60 g. of protein and about 100 g. of fat only needed 42+22 units, and the blood sugar was below 200 mg. throughout the day without any symptoms of hypoglycaemia.

It is still difficult to give statistical evidence that patients suffer harm from having persistent hyperglycaemia. The patients whom I treated in 1923-4 and who refused to keep to the strict diets of those days certainly died much more quickly than the ones who kept to their diet (*Lancet*, 1938, 2, 1), but some of them lived much longer than I expected. Nowadays the amount of carbohydrate in the diet is so much more generous than what I used then that it is rare that I find patients who do not stick to the diets, and with the aid of insulin they maintain a reasonable control of the diabetes so that I have little opportunity of telling whether patients do better or worse with continuous hyperglycaemia.

Dr. Luntz rightly points out that arteriosclerosis does not occur as a result of hyperglycaemia, and this complication is now accepted as being due to the low carbohydrate-high fat diets used for the first 6 years or so after the introduction

of insulin. The complication I dread is that of retinitis and cataract. Hyperglycaemia is not the only factor in the production of these conditions, and I have seen retinitis develop in elderly diabetics although the blood sugar has been well controlled. I have much more often seen it in patients who have had an uncontrolled diabetes for some years, and I have watched the retinitis improve when the diabetic condition has been brought under control. I believe that patients who are allowed to have a blood sugar above 250 or 300 mg. throughout the day run much greater risks of this complication. Prof. Micks says we shall know in 20 years, but by that time many patients may have suffered much from impaired eyesight. It seems a risk too great to be taken with our present knowledge.—I am, etc.,

London, W.1.

GEORGE GRAHAM.

Neonatal Gastro-enteritis

SIR,—I was much interested in Dr. J. L. Henderson's article on neonatal gastro-enteritis (April 3, p. 410) and in his letter (May 15, p. 613).

During the months of February, March, and April, 1942, I used sulphaguanidine in the treatment of seventeen cases of this disease. The cases occurred in the nurseries of the Royal Maternity Hospital, Belfast. Fifteen were in premature babies whose average weight was 3 lb. 8 oz.; the remaining two were in full-term babies.

Two of the patients died; therefore the mortality rate was just under 12%. For the purpose of comparison I looked up the hospital records of cases of this disease during the years 1938 to 1941 (inclusive). During this period there was a total of 58 cases of gastro-enteritis with 20 deaths—i.e., a mortality of slightly over 37%.

The treatment given was as follows: The affected babies and all "contacts" were isolated. Feeding with breast-milk was continued. The breast-milk was obtained from nursing mothers either by hand expression or by a breast pump. Sulphaguanidine 0.125 g. was given four-hourly. This dosage was continued till the stools were normal in frequency, colour, and consistency. In only a few cases was it thought necessary to administer Ringer's solution subcutaneously.

My results suggest that smaller doses than those recommended by Dr. Henderson will give good results. I agree that it is necessary to give an adequate fluid intake, but I think that it is unwise to discontinue feeds with breast-milk. Breast-milk can be obtained, and I think that a baby requires its natural food as urgently during illness as during health. Fortunately vomiting was not a marked feature of the cases I saw, and therefore feeding did not present any unusual difficulties.

I agree with Dr. Henderson that controlled experiments are not justifiable when dealing with this disease. The dividing line between life and death in these cases is very narrow. Further, these babies are frequently those from difficult obstetric cases, and therefore one is not justified in carrying out controlled experiments with them. While clinical impressions may be incorrect, it is impossible not to be favourably impressed when the evidence can be seen growing stronger and heavier every day. Experienced members of the nursing staff in the hospital who had witnessed other outbreaks of this disease were certainly favourably impressed by the results obtained. In fact, I doubt if they would have permitted a controlled clinical experiment.—I am, etc.,

G. A. CRAIG, F.R.C.S.E.D.,

Late Senior Obstetric Tutor,
Queen's University, Belfast.

Ayr, Scotland.

Epidemiology of Diphtheria

SIR,—I admire the caution of your conclusions in the leader on "Epidemiology of Diphtheria" (July 10, p. 44). One must in drawing conclusions from statistics in this disease take into consideration the capricious behaviour of the bacillus, as the following notes on a small epidemic in an isolated village show. The epidemic occurred eight years ago, before the days of immunization. The cases numbered 11 and the epidemic lasted two weeks.

1. The children affected (with one exception aged 7+) belonged to one class of the village school who were between 6 and 7 years of age, and the cases occurred at irregular intervals over a fortnight.

2. All the children affected (with the same exception) were inmates of sublet single apartments.

3. Every child had a brother or sister who occupied the same bed, but none of these was infected.

4. All the children of the school were examined regularly, swabs from suspicious throats being examined.

5. The origin of the epidemic was found to be a child of 3 years with chronic nasal diphtheria whose brother was a member of the class. Swabs from throat and nose of the brother were negative.

6. The epidemic ceased immediately these two were isolated.

Since this experience I have noted how seldom swabs from contacts in a family where one member has tonsillar diphtheria are positive, and how universal the infection if the disease is nasal. It may be that the infectivity of the disease increases with the duration of the infection.—I am, etc.,

Bathgate, West Lothian.

JOHN F. LANG.

Rehabilitation

SIR,—In Dr. Harold Balme's article on "Some Problems of Rehabilitation" (July 10, p. 47) he makes a number of points with which all consultants in physical medicine will agree but there are others that call for immediate comment lest worse befall the patient in the future than in the past.

The points which will meet with warm agreement can be enumerated as follows:

1. "The effect of trauma on every type of soft tissue—fascia, muscle, tendon, serous and synovial membrane, etc.—demand careful study. . . . It should not, however, be difficult, by means of controlled experiment carried out on a sufficient number of cases, to establish definite criteria by which to judge of the method suited to each class of disability and to each stage of recovery."

2. "Nothing would be more unfortunate than for rehabilitation to be divorced from medical or surgical control and established as a new health cult."

3. "In the first place, what do we mean exactly by rehabilitation? It is an unfortunate and clumsy term, and one which is already being used with a variety of different meanings, but from a strictly medical and surgical aspect it can perhaps best be defined as the method by which physiological function is fully restored after its temporary loss from injury or illness."

With regard to No. 1, physical medicine has for more than 20 years asked the Medical Research Council and other bodies for funds for definite investigation and has always met with a polite but firm refusal. There is no indication in Dr. Balme's article that such funds are anywhere in sight. Without them his premisses are but the paper recommendations we have all made over many years. Can he tell us whether the Ministry of Health is prepared to be generous and sponsor the investigation he calls for? Its actions up to date give less than hope that adequate investigation of physical methods is, or has ever been, part of its programme.

As all physical medicine consultants will agree with No. 2 this calls for no comment.

In reference to the definition of rehabilitation, it is possible to agree with Dr. Balme's description of the term as "unfortunate and clumsy," but his definition should have these words added: "and begins with the onset of the injury or illness." Rehabilitation is neither a new nor a separate subject.

So much for those aspects of his paper about which the practitioners of physical medicine can agree. In his paragraph headed "Organization of a Rehabilitation Team" he falls, however, into the fallacy (or is he being merely diplomatic?) so common, particularly among orthopaedic surgeons, that, by referring a case to a medical man with special training in physical medicine the physician or surgeon is losing control over the patient. He states that his "prescribers will of course consist of the physicians and surgeons actually in charge of the patients, whose duty it is to signify when rehabilitation should start." By this proposal he suggests perpetuating the worst features of inefficient physical medicine departments by putting those cases whose treatment the staff wish to delegate into the care "of one or more members of the whole-time medical staff," presumably a house-physician or other junior practitioner inexperienced in physical medicine. There is really no difficulty about the position or relations that should exist between members of the staff and the specialist in the medico-physical aspects of health and disease. All that is required is to adopt certain simple rules that have been in operation at the Royal Free Hospital for twenty years. These are:

(a) "Will Dr. — kindly see and treat"—i.e., a complete transfer of the case to the physician in charge of the department.

(b) "Will Dr. — advise re treatment?"—i.e., the case is seen a report made, and the staff member decides whether to accept the advice or not. These patients see the referring member of the staff at stated intervals, if physical treatment is decided upon, and remain under him.

(c) "Will Dr. — please give short wave, etc." These cases are treated by the recommended method unless technical considerations strongly contraindicate it, when the case is referred back with a report. These cases also remain under the member of the staff referring them. It is also understood that if a member of the staff wishes to insist on particular types of treatment the facilities of the department are at his disposal. But he must be sufficiently acquainted with all the techniques to be able to carry them out himself. From the patient's point of view is not this "a minimum reasonable requirement"?

Under the Royal Free Hospital rules full liaison exists and the consultant is able to develop and evaluate new techniques. Under Dr. Balme's proposed organization with multiple control, or only subordinate staff control, the departments would inevitably degenerate into "radiant heat-faradism-massage" annexes, as I have seen on all too many occasions, and occupational therapy rooms would become places where "arty-crafty" gadgets are made under the dignified name of diversional therapy. I confess I do not understand his "co-ordinating officer"—apparently non-medical.

Bring together, under a first-class clinician, rehabilitation, physical medicine—call it what you will, so long as it includes full access to proved physical methods, whether electrical, hydrotherapeutic, massage, exercises, physical training, or occupational therapy—and have rules of procedure agreeable to members of the staff and provision for research and then rehabilitation will secure an honoured place in medical work, and Dr. Balme's review will have served a valuable purpose.—I am, etc.,

London, W. 1.

C. B. HEALD.

X Rays and the Colon

SIR.—In your issue of July 10 (p. 51) you report a discussion at the Proctology Section of the R.S.M., and in so doing the impression is given that Sir Arthur Hurst gave a warning against the use of x-ray diagnosis in diseases of the colon, although his words may have applied only to colonic spasm. In any case I feel obliged as a radiologist to comment on his statement, which may otherwise give rise to misunderstanding of the place of x rays in investigating the large bowel.

There is no viscus more readily examined radiologically than the colon in most of its length, and there is no one method of investigation so productive of information, although it must be repeatedly pointed out to clinicians that a radiologist's report is only offered as one link in the diagnostic chain, and it is unfair to place the responsibility of diagnosis upon any one such link. The colon may be filled with barium, either from above after a barium meal, or from below by a barium enema, and the former method gives little information unless gross abnormality is present, such as almost complete obstruction. By a barium enema, administered after thorough cleansing of the colon, the lumen may be entirely filled and deformities due to obstruction—tumours, diverticula, and the different types of colitis—visualized. Examination of the residue left after evacuation, with air inflation if desired, gives further valuable information about the state of the mucosa.

Presumably there is no real challenge to the value of x-ray diagnosis in the gross obstructive and deforming lesions, but in the investigation of cases of colitis and minor derangements of bowel function a word may be needed: Division of constipation cases into the types of rectal dyschezia and colonic constipation is readily made from the gross dilatation of the rectum seen in the former and the abnormal haustration and mucosal pattern of the latter, and, of course, organic disease of the colon is at the same time eliminated to a large extent—a point of great value, as the question of malignancy has to be considered in most cases. Ulcerative colitis shows well-marked radiological signs in all its stages, from the early irritable and pin-pointed mucosa to the late hose-piping and infiltration.

Sir Arthur Hurst very clearly points out the fallacy of diagnosing mucous colitis, but on this question of spasm and colonic catarrh a good deal of radiological evidence is available. A simple catarrhal colitis is often seen, with general excess of sticky mucus and widespread tenderness and spasm; and a chronic colitis, also associated with spasm, is recognized radiologically, and is by many regarded as one of the allergic family, and it is presumably this condition to which he specifically refers. Spasm is a most obvious thing radio-

logically, and it is difficult to see any objection to reporting on its presence and suggesting a diagnosis.

Finally, a word of caution may be offered as to one province in which the radiologist may be misleading, and that is in conditions affecting the upper rectum and recto-sigmoid, as this region is most difficult to visualize and radiograph owing to the overlying coils of sigmoid, and unless a clear view is obtained during the filling very little more is seen and an early ring carcinoma may be missed. Fortunately this distal colon is easily examined directly, and proctoscopy and sigmoidoscopy are definitely needed to supplement x-ray investigation of the colon.—I am, etc.,

Hove.

E. MILLINGTON, D.M.R.

Aspirin and Gastric Haemorrhage

SIR.—The inflammatory reaction to aspirin seen in the gastric mucosa is limited to the immediate vicinity of the granules adhering to the stomach wall. This fact and the rapidity of development of the changes point to the action being a local one, and not a post-absorption effect as suggested by Dr. M. Honigsberger (July 10, p. 57). If further proof be needed it is supplied by the observation that calcium aspirin in solution has no effect on the gastric mucous membrane.

In regard to Sir Arthur Hurst's letter (June 19, p. 768) we should, I think, be careful not to include under aspirin-induced haemorrhage examples of sufferers from gastric or duodenal disease who have bled after taking the drug. It may indeed have provoked the bleeding, but it can be argued that it would have occurred in any case. It is by no means uncommon in a case of duodenal ulceration for haemorrhage to arise during a period of complete freedom from pain. I have recorded only those patients who have taken aspirin for pain not arising in the alimentary tract. If they bled yet recover quickly with no trace subsequently of indigestion or radiological abnormality, it is reasonable to inculpate aspirin as the cause.—I am, etc.,

London, W. 1

A. H. DOUTHWAITE.

The Nation's Milk

SIR.—In the proposed alterations concerning an improved milk supply the term "accredited" is retained. Surely this misuse of language should not persist. If a substance is "accredited" the public may rightly expect it to be trustworthy. The standard of bacterial purity required to reach "accredited" grade is so low that milk sold as such may still contain the living organisms of such diseases as tuberculosis or enteric fever. Veterinary inspection of herds once a year will not suffice to prevent such germs from reaching children whose parents think in supplying them with "accredited" milk they are thereby securing safety.—I am, etc.,

Northwood, Middlesex.

ESTHER CARLING.

Intravenous Technique in Infants

SIR.—Dr. D. MacCarthy's paper (July 10, p. 36) on venoclysis was most welcome. He is to be congratulated on the scrupulous care he exercises, and uniformly good results are possible only with such care. Michelangelo's dictum, "Trifles make perfection and perfection is no trifle," must be remembered. Putting up a drip on a six-weeks-old infant is a great test of skill and patience, but it is a most satisfying operation when completed. Alterations such as the slight plantar flexion of the foot make the whole difference to the success or failure of the operation. Some points which I have learned by failure are, I think, worth mentioning.

This operation is often performed at night, and most difficulties seem to occur also at this time. Therefore a strong, powerful light is a *sine qua non*. Stooping over a low cot puts a strain on the operator; it is better to kneel by the cot. The instruments must be placed so that they can be got at easily without turning or stretching. Babies with fat ankles are often the most difficult, and little blobs of fat make the detection of the vein difficult. A pair of scissors such as those used by ophthalmic surgeons are a great aid in making a suitable "nick" in the vein. A severed vein does not mean failure; it is usually possible to pick it up and use it. A very fine forceps is most useful in picking up the V-shaped piece of vein preparatory to the actual insertion of the cannula. Getting the lip of the cannula into the vein is the most difficult part of the operation: once in, the remainder of the cannula slips in easily. I have succeeded in getting a full-size Hamilton Baile;

cannula into the saphenous vein of a baby five months old. Dr. MacCarthy's suggestion to retain the stylet in the cannula is an excellent one. After suturing the wound, the ligature can be passed through the holes in the wings of the cannula and tied. This prevents any movement of the cannula within the vessel, and in adults one can entirely dispense with a splint. The Baxter equipment is very easy to handle, and the rubber tubing is better than that supplied with E.M.S. sets. The latter is too stiff and has a spring-like action. On two occasions as I was about to tie the proximal ligature on the vein torsion on the tubing pulled the cannula out. Frequent swabbing and probing most certainly lead to sepsis. Also, one should never try for the vein higher up in the leg when one has failed lower down. The remaining point to discuss is—Which is the better, needle or cannula? We lose the vein for future use by cutting down on it and using a cannula. This is important in cases where repeated transfusions at intervals are required—e.g., blood diseases. Young diabetics if not stable may also require repeated infusions. In adults the needle is the method of choice for a single infusion, but for continuous infusion a cannula is better.

Finally, "blood is thicker than water." A blood transfusion in an infant often spells failure for the intravenous method. Blood will not run through a small needle or cannula even though saline will. Other methods such as giving it into the superior sinus or into the bone marrow may then be tried. Intraperitoneal infusion for saline must also be remembered. I am sure that papers giving full details about the practical side of these methods would be appreciated by all those interested in paediatrics.

—I am, etc.,

WILLIAM CAHILL.

Blood Grouping in Tubes

SIR.—The annotation on blood grouping (June 19, p. 764) emphasizes three cardinal points—namely, that accurate grouping is not a simple procedure; that grouping on cells and serum is essential; and, lastly, that it is desirable to use the tube technique. The M.R.C. War Memorandum (No. 9, H.M.S.O., 1943) sets forth the essential points and should be carefully studied by all concerned with blood grouping. In the light of my own experience in the Welsh Board of Health regional transfusion laboratory I should like to emphasize the great value of grouping in tubes. In the past three years upwards of 25,000 grouping tests have been performed per annum. From June, 1940, till August, 1942, all tests were performed on slides, and the majority were grouped on cells only. In August, 1942, grouping on glass slides was completely discarded in favour of tubes in view of Dr. G. L. Taylor's article on a reliable technique for the diagnosis of the ABO groups (*J. Path. Bact.*, 1942, 54, 81). The tube method has revealed many errors made by the slide technique, and we have repeatedly had cause to be very thankful for the change over. It does mean extra work in the laboratory and more precise technique, but it is significant that the technicians prefer the tube method. Without exception all grouping is performed on cells and serum. If the latter is not available a further specimen is asked for.

A larger tube than that recommended by Dr. Taylor is used, the size being $2\frac{1}{2}$ in. \times 2 in. (1 cm. \times 5 cm.). Such a tube is convenient because it is easily cleaned. Larger volumes are used—namely, four drops each of saline, serum, and citrated cell suspensions. Tubes are stood 15 minutes and then centrifuged for 2 minutes at 1,500 to 2,000 revs. per minute. Beautifully clear-cut readings are obtained. With the tube-centrifuge technique it has never been necessary to use the microscope. Alternatively, tubes may be left to stand 4 hours (or overnight) on the laboratory bench and then read; the agglutinates are much larger and coarser than those obtained with the small tubes and smaller volumes recommended. I would emphasize the importance of using a thin rather than a thick suspension of cells.

A disconcerting discovery was that O had sometimes been wrongly diagnosed by the slide technique as AB or A, or A labelled O, etc., and the causes of these errors were largely cold or pseudo-agglutination. Routine grouping on serum effectively checks the results of grouping on cells and renders errors almost impossible, especially if tubes are used. Since using tubes we have eliminated well over a hundred errors, but there must be more because large numbers of persons grouped on cells by the slide technique only have not had their groups rechecked. The importance of correctly diagnosing O requires no emphasis, and I believe that this can most

reliably be done only by grouping on cells and serum in tubes. The same of course applies to the other groups. I do not know what the percentage of errors is with the slide technique, especially when cells only are grouped, but I doubt if it is less than 1% in inexperienced hands, and it is probably more. Some years ago I observed two fatalities due to incompatible blood transfusion. Both were due to grouping on cells only and to faulty grouping by the slide technique.—I am, etc.,

Cardiff.

R. DRUMMOND,
Regional Blood Transfusion Officer.

Blast Injuries

SIR.—I have read (with delay) what Major J. V. Wilson states about the possible causes of death in blast injuries from high explosives (April 17, p. 470). Though not a pathologist, I have had occasion to examine a large number of corpses of civilian war casualties. Blast injuries were common, but these were generally associated with other lesions such as burns, splinter wounds, lesions to the skull from a knock against the ground or wall, etc. Only a very few cases could be considered as pure blast cases.

On one occasion I performed a post-mortem examination on two sisters, aged 8 and 13 years respectively, who had died in a badly constructed rock shelter in front of the only entrance to which a very heavy high-explosive bomb had burst. The dead children were found lying down in their sleeping-cots, and it was presumed that they must have been killed from blast injuries without having been knocked. External examination showed no lesion whatever. The abdominal viscera were markedly congested all over; the lungs had all the haemorrhagic lesions which Major Wilson portrays with perfect faithfulness in his paper. But most interesting was the condition of the brain. There was no lesion whatever in the scalp, skull, or dura mater, but this was on the stretch, and when cut through, the brain bulged out under excessive tension. On removal the brain was found very large, with flattened convolutions, very oedematous, and markedly congested; no haemorrhages were noticed.

The condition of the brain recalled the clinical observation that many wounded exposed to blast had presented on admission to the Central Hospital all the signs that are usually associated with cerebral concussion—unconsciousness or drowsiness, amnesia, irritability, headache, etc.

It is suggested that lumbar puncture and repeated enemas of magnesium sulphate may be of benefit in the early treatment of blast cases. No attempt was made to check the utility of this conclusion, as it was reached only when aerial bombardment on the island on a large scale had nearly come to an end.—I am, etc.,

Malta.

WALTER CANADO.

Psychiatry in General Hospitals

SIR.—Under the above heading (June 12, p. 735) we adduced positive evidence in demonstration of the striking success of the voluntary system in mental hospitals by application of the provisions of the Mental Treatment Act, 1930. In replying to Dr. Crichton-Miller's and Dr. Minski's observations (June 26, p. 800) we would point out that both correspondents are at pains to find objections to the mental hospital which our voluntary patients (mainly psychoneurotics) have themselves already learned to surmount.

In stressing so particularly "the locked door" of the mental hospital, Dr. Crichton-Miller has chosen a singularly inapposite objection. Our gates are open night and day; moreover, out of eight male wards one only is kept locked—the so-called closed ward. A similar though less extensive arrangement holds good on the female side, and all our villas where the psychoneurotic cases are housed are conducted entirely upon the open-door principle. By applying such a word as "condemned" to those who freely place themselves under care Dr. Crichton-Miller reveals a prejudiced outlook; he surely can have no true conception of what the mental hospital to-day is really like.

Turning now to Dr. Minski's letter, he begins by simply begging the question as to whether the so-called neuro-psychiatric unit does in fact succeed in inducing people to undergo early treatment in those alleged cases where the mental

hospital is said to fail. We have already shown that, despite the proximity of chronic patients properly segregated, patients are not in fact deterred from voluntarily seeking admission to mental hospitals, and this accounts for our high increase in admissions, during the past ten years. Dr. Minski attributes to us, by the interpolation of words we did not use, assertions which we ourselves avoided. We made no claim that the mental hospitals "originated" the modern physiotherapeutic treatments; the exact phraseology was "initiated and evolved," and Dr. Minski might refer to Drs. Andratsche and Rogerson's article on page 780 of the issue in which his own letter appears, which says of electric convulsion treatment that "credit for the introduction to this country must be shared between Fleming, Golla, and Grey Walter (1939) and Shepley and McGregory (1939)."

Stigma is the social ostracism that is attached to any mental illness, and will exist so long as the general opinion towards mental disorders remains unenlightened. The mental ward of the general hospital labours under the same stigma as the mental hospital, despite the introduction of euphemisms such as "neuropsychiatric wards," and the dropping of the word "mental." Furthermore, the general hospital is neither situated nor equipped so as to be able to provide those occupational and recreational facilities which are indispensable adjuncts in the rehabilitation of the mentally afflicted.

In conclusion we would urge that the requirements of mental treatment to-day are such that the patients' interests are best served by their being treated in a hospital designed, equipped, and staffed for the purpose—in short, a mental hospital.—We are, etc.,

T. P. REES.
W. H. SHEPLEY.

SIR.—Dr. Minski's statement (June 26, p. 800) that the modern physical treatments in psychiatry originated in American and Continental neuropsychiatric clinics and not in mental hospitals contains several mistakes. While insulin treatment and electrically induced convulsions were first applied in university clinics, Meduna initiated convulsion treatment and Moniz performed his first leucotomies in mental hospitals. University clinics on the Continent are frequently not part of a general, but of a mental, hospital. I do not know of any method that originated in America, but American psychiatrists have applied all those mentioned on a large scale in their varied types of hospitals.

There is no doubt that, as Dr. Minski points out, a great variety of treatment facilities for psychiatric cases is desirable. If one remembers the long pre-war waiting lists of many psychiatric institutions and the large number of psychiatric patients only recognized as such after being called up to the Services, it is difficult to understand why specialists should now quarrel where they should be treated. Those who welcome with enthusiasm psychiatric wards in general hospitals seem to forget that these are already in existence. May I briefly refer to two of them in different parts of Britain.

One of these hospitals belonging to a progressive municipality has a psychiatric department with well over 600 beds and a yearly admission rate of 700 patients. The "observation ward," containing approximately 100 mental defectives and the same number of senile dementias, has one doctor, who during recent years was not a psychiatrist. There are no treatment facilities. A somewhat similar psychiatric department forms part of the other hospital, for which the corporation is responsible. It was originally intended for neurotics, but is now filled with 400 psychotics, many of them of the chronic type. There are one full-time psychiatrist and two visiting specialists, and the therapeutic possibilities are only slightly better than in the institution first referred to. Both places, although parts of general hospitals, are in fact merely dumping grounds for patients who, for one reason or another, cannot be admitted to the mental hospitals, where they would receive suitable treatment.

I would suggest that these facts show that successful psychiatric work depends not on the type of hospital but on proper staffing and equipment—in other words, appreciation of the authorities of their duties towards the mentally ill and the dimension of the social problem of psychiatry.—I am, etc.,

Richter Royal, Dumfries.

W. MAYER-GROSS.

Resuscitation by Rocking: Adaptation for First Aid

SIR.—Dr. N. Howard Mummery's rocking apparatus for Eve's method of resuscitation (June 19, p. 759) would appear to be excellent for, as he says, rescue stations, also ships, hospitals, etc. It is, however, not particularly suitable as a portable adjunct to first aid.

The N.C.O.s of the medical section of this battalion, along with the director of the Civil Defence first-aid posts in the district, have given some time to the study of the possibility of applying this rocking method to first aid. They believe it to be, from what they have read on the subject, the most efficient method yet known. The technique is easy to learn. It is much less arduous and more foolproof than any previous

FIG. 1

form of artificial respiration, and, once it has been set in motion, it can be carried on by quite untrained personnel. For these reasons it would appear to be the method of choice.

To take the place of the rather cumbersome apparatus described by Dr. Howard Mummery we are having a little "gadget," of which I enclose a sketch, attached to all our stretchers of the Army type—a pair to each stretcher. It is, in essence, merely a grip to slip over any available pole, hayfork handle, fence, rope, paling, etc., so that the rocking of the stretcher may be carried on. The gadget is of the "lazy-block" pattern, and has been made for me by Mr. Robt. Colquhoun, chief engineer of Messrs. Baird and Dalmellington's Fauldhead Collieries. It consists of a base plate which is fixed to the centre of each stretcher pole by four screw nails. From the plate arises an attachment for fitting over the pole, bar, etc., on which the rocking is to be done. It is easy to make, and there should be little or no expense incurred in converting

FIG. 2

Army type stretchers into rocking stretchers. We have tried it out in practice and we think that it works. It may be open to some grave criticism—if so it can easily be scrapped. We claim no patent rights, but, if acceptable, it might perhaps be known as the "Kirkconnell" adaptation.

It seems only fair that the men who have worked for a forward step in first aid should be known; their names are Sergts. A. McAnespie and J. Torrance, and Cpl. D. Hastings of this battalion, along with Mr. Robert McCormick, Civil Defence First-aid Post Controller, Upper Nithsdale. The sketch of the gadget has been made by Lieut. G. Broadfoot, Kelloholm.—I am, etc.,

BOWMAN EDGAR.
M.O., 4th Bn., Dumfriesshire H.G.

Kirkconnell, Dumfriesshire.

Artificial Respiration

SIR.—Dr. E. Granger (July 3, p. 23) propounds a "swing-boat" method of artificial respiration. His arguments are based on inaccurate mechanics. Eve's rocking method over some fulcrum below the centre of gravity of the patient is the more efficient from any slight body slide; which is arrested by the friction of clothing or by suitable straps, the inertia of the

viscera thus having a succussive effect. The extra effort needed to reverse the position encourages the necessary slow steady rate, with a pause at the limit of each excursion. Centrifugal force is negligible. The method is highly efficient even in unskilled hands.

The "swing-boat" has a self-stabilizing horizontal position and an easy natural period, as has any comparable device of linkage producing rotation about a virtual fulcrum above the centre of gravity of the patient. When it is worked steadily at that period (as it would obviously be) it subjects the viscera to no great longitudinal displacement, but to centrifugal force in a dorsi-ventral direction only!

Personal experience will show that one is unable to resist the rhythm of Eve's method, whereas the prone position on a swing induces no respiratory compulsion.—I am, etc.,

London, S.W.1.

D. STENHOUSE STEWART.

Treatment with Tuberculin

SIR,—I am much interested to see the correspondence on the use of tuberculin in your issues of June 12 (p. 736) and July 3 (p. 19).

I used Dr. Camac Wilkinson's method very extensively from 1910 to 1913, and again in 1918 as tuberculosis officer in Portsmouth, and published the full account of the methods with the results I obtained in a book called *Dispensary Treatment of Pulmonary Tuberculosis*, published by Baillière, Tindall and Cox. Circumstances made it difficult to follow up the after-history of the cases since 1919, except in a certain number of private cases which have confirmed the value of the remedy. I have not been engaged in medical work since then, but in the course of social welfare work during this war have had contact with a tuberculosis dispensary and have been disappointed to find that there appears to be no improvement in the treatment of the disease to justify giving up a remedy which, although not perfect, gave very satisfactory results in a great proportion of cases. The recent development of x-ray diagnosis should greatly increase the confidence with which tuberculin treatment could be used and the results estimated.

If any of your readers would find the study of my cases in Portsmouth useful and is unable to obtain a copy of my book, I shall be glad to lend a copy.—I am, etc.,

Ashtree House, Horton Kirby, Kent.

HILDA CLARK.

Subcutaneous Ligature of Varicose Veins

—Although I do not consider the method of Major Goldstone is the ideal surgical treatment of varicose veins, there is no doubt that many cases will not respond to injection treatment no matter how skilfully applied, and some form of surgery is necessary. However, to suggest, as Mr. R. R. Foote does (July 3, p. 22), that the surgical mortality is a serious matter is plain nonsense. I have performed or supervised the ligation at various sites of several hundred cases without a death, and I know of several large series which have been equally successful.—I am, etc.,

Brentwood.

W. D. PARK.

The Cult of Negative Health

SIR,—The argument propounded by Dr. Alan Maberly (July 10, p. 55) that the environment must be sufficiently unfavourable for the living organism to thrive is nothing but the crude Darwinian theory of the struggle for survival which gave nineteenth-century *laissez-faire* its pseudo-scientific benediction. It is a doctrine adopted, significantly enough, by our Nazi and Fascist enemies, who extol the virtues of hardship and blood-letting as a race invigorator. The rest we know to our cost and peril. A second world war is being fought to put an end once and for all to a "jungle" struggle for survival, and at its victorious conclusion to extend to mankind for the first time a modicum of ordered security in a world of fellowship.

To preach the salutary effect of "an environment sufficiently unfavourable" in these days of agonizing human effort and suffering is proof of an approach completely out of touch with current social realities. Does Dr. Maberly think (for his argument implies as much) that absenteeism in the coalfields is due to the environment—i.e., the

conditions of labour—not being unfavourable enough—to stimulate the men to greater efforts? One can imagine the reception such a doctrine would have if preached in South Wales, Tyneside, or the Clyde.

Furthermore, I do not accept the analogy between the living organism and society as postulated by Dr. Maberly. Society is a congeries of classes and sects, political and economic, shut through at various levels by a diversity of religions. Order and stability are at best a precarious compromise dependent upon the relative predominance of a class or sect at a particular period. Society is never homogeneously soft or fat; indeed it is only because one section of the community is fat that the other is thin, and in our particular state of social organization this is a necessary condition of affairs.

In the modern world Russia alone gives the lie direct to the argument that "not only has a greatly improved standard of health been accompanied by an increasing tendency to hypochondria, but an equally great improvement in social services and economic security has run parallel with increased anxiety about the future, with lessened individual self-confidence and self-reliance." There (before the war) steadily rising standard of living has gone hand in hand with a steadily diminishing incidence of neuroses of all types (see Williams, F., *Soviet Russia Fights Neurosis*, 1933), plus fearlessness and an optimism heightened by the quiet confidence of the individual in his and his country's future. Present events confirm this. The inherent danger of the arguments put forward by Dr. Maberly and by Dr. R. E. Lucas (June 1 p. 766) is that they play straight into the hands of the reactionaries who see in every attempt at social amelioration the nefarious work of Satan, who would set free idle hands for evil purposes.

Surely there is suffering enough in the world without emphasizing the danger of waxing soft and fat in an environment not sufficiently unfavourable. Time enough when such physical calamities as cancer and tuberculosis have been conquered, and when social diseases such as economic and political injustice have been laid low, to talk of softness and waxing fat. We should not forget that man creates his own environment and so badly has he adapted himself to it that he is in grave danger of extinction through a variety of causes all in the power of man to eradicate. It seems to me most inopportune to stress the need for an unfavourable environment in such days. On the contrary, it is our duty to adopt a "positive" attitude and to define our conception of a favourable environment as one to struggle for its achievement.

For me, at any rate, a favourable environment is one in which man can express his physical, mental, and spirit capacities to the full in a harmoniously integrated personality and so achieve positive health: a *sine qua non*, a state of political and economic democracy. To-day we are committed to scientific industrialism. The problem of post-war leisure and "practical problems" which have caused Dr. Lucas's misgivings are complementary and interconnected. We cannot enjoy the one without facing up to the other. In a world already contemplating a little fearfully the problem of post-war mass unemployment such misgivings about our future of leisure are completely out of court in this context. In last analysis it is not a question of how many or how few electrical gadgets a country housewife may or may not possess but the old problem of the State and her sense of community within it.—I am, etc.,

Bush Hill Park.

W. LESTER, M.J.

Medicine and Politics

SIR,—It seems that the well-disciplined armies now mobilized against the idea of change and development in our medical services must be provided with banners in the form of clichés which exert a hypnotic effect upon them and lead them to the attack. That well-worn slogan, "Free choice of doctor," still inspires many, perhaps the majority of who have acquired the bulk of their patients by purchase from their predecessors. Dr. Geoffrey Bourne, appealing to a section of medical interests, has raised as his standard the sacred name of science. Some of his supporters may find it difficult to live up to this rallying-cry.

Controversy becomes easier when it can be expressed in such simple and colourful pictures as that of the noble p

of science set upon by the black-hearted politicians (in the scientific words of Dr. Bourne, "either ignorant, incompetent, or dishonest"). The fact is, of course, that many of the present deficiencies in our medical services have nothing whatever to do with "science," and Dr. Bourne cannot be allowed to evade these matters by such an easy device.

Let us take a simple example from the field of hospital services. A member of the public in need of hospital treatment seeks admission to a voluntary hospital. He finds that his chances of early admission to the hospital of his choice are infinitesimal, but they can be greatly increased if he is able to pay a private fee and consult a member of its honorary staff. If he feels this to be wrong, to whom should he appeal—the "scientists" or the "politicians"? (If Dr. Bourne doubts whether such a situation frequently arises, I can furnish him with particulars of some recent examples at hospitals well known to him.) Such matters are of more immediate concern to the people whom we serve than the abstract claims of "science," and if we believe in democracy, as Dr. Bourne does, we must concede the people's right to protest against them and the duty of democratic government to remedy them. Perhaps it is considerations of this kind which have given rise to the development of municipal hospital services. At present more than 80% of the hospital beds required by the people of London have to be provided by public authorities, and this would not be necessary if voluntary organizations had proved equal to our needs.

Municipal hospitals, like other institutions, have their faults, and it is easy (and legitimate) to criticize them. From the public's point of view, however, they have one simple virtue: they are *responsible to the public* for the provision of hospital treatment to those in need of it. For the very large proportion of patients suffering from diseases of the types which are unpopular in "scientific" institutions, this virtue outweighs many disadvantages.

Science, too, has its claims, and if Dr. Bourne is familiar with the magnificent public authority hospitals in countries where voluntary hospitals are unknown (for example, in Scandinavia), he must realize that science can and does flourish in such hospitals. In attacking the relatively archaic form of organization of our own municipal hospitals Dr. Bourne is largely tilting at the windmills, for their organization will undoubtedly develop and progress as do their standards of treatment. Those of us who work in municipal hospitals are not blind to their faults nor unconscious of their opportunities for development and improvement.—I am, etc.,

London, W 9.

A. L. JACOBS.

Conditions for Good Work

SIR.—The average doctor is inarticulate, has no time for thinking or writing, and after recent events is more fatalistic than ever; it is therefore the extremes of opinion that are voiced. Of all that has appeared in print Mr. Wilfrid Adams's letter (July 10, p. 53) most nearly expresses the feelings of the average general practitioner and goes to the root of our present difficulties—namely, numbers.

Most of our troubles, both those mentioned by Mr. Adams and others, can be abolished, but only by a great increase in the numbers of the profession. State interference is now necessary because the average income cannot afford full and efficient up-to-date medical service; so the main feature of that interference should be financial subsidy. Given the money and the personnel, success could be achieved without making devastating changes: lacking either, any scheme must fail.

It is essential, therefore, by offering reasonably attractive prospects and by other means, to ensure an adequate supply of recruits and greatly increase the numbers of the profession: otherwise a vicious circle may develop with great detriment to the good of the community.—I am, etc.,

York.

CHARLES C. COBB.

It is generally agreed that the solanaceous alkaloids are useful in the symptomatic treatment of Parkinson's syndrome. H. Volmer (*Arch. Neurol. Psychiat.*, Chicago, 1942, 48, 72) concludes from his own experience that a combination of alkaloids is more effective than any one given separately, and found that the best mixture is 90.2% hyoscyamine hydrobromide, 7.4% atropine sulphate, and 2.4% scopolamine hydrobromide.

Obituary

The recent death of HUGH WELLS ARMSTEAD at Seaton, Devon, whither he retired on giving up practice in London some years ago, removes one of those very highly qualified and gifted members of the profession who fifty years ago did not disdain the status of general practitioner but are now much more likely to adopt a specialty. He was educated professionally at St. Bartholomew's Hospital and School, where he was successively exhibitor, junior scholar, senior scholar, and senior house-surgeon. He qualified M.R.C.S., L.R.C.P. in 1892; M.B., B.S. Lond., with 1st-class honours in medicine; M.D. Lond. and F.R.C.S. Eng., both in 1894—a record which speaks for itself. He was for a long time a well-known London general practitioner, and published his reminiscences and reflections entitled *Thirty Years of General Practice*. Outside his professional interests, his leanings may be gathered from his *Artistic Anatomy of the Horse* and his contributions to the *Magazine of Art* on similar topics. For several years he was a member of the Council of Epsom College, until increasing deafness and his departure from London led to his resignation. He had been a good friend to the College, and to its library, as well as a regular subscriber for many years.

Dr. GERALD S. EWEN, of East Twickenham, who died on June 26 at St. Bartholomew's Hospital, joined the B.M.A. in 1912 and was chairman of the South Middlesex Division in 1924-5. He was born in Jamaica in 1877 son of the Hon. William Ewen, and from Lord Weymouth's Grammar School came to England to study medicine at Bart's, qualifying M.R.C.S., L.R.C.P. in 1902. During the last war he served in Salonika with a temporary commission in the R.A.M.C. Dr. Ewen had been honorary medical officer of St. John's Hospital, Twickenham, since 1921.

Lieut.-Col. H. C. Keats, I.M.S. (ret.) writes: It was with great regret that I read of the death of Lieut.-Col. H. J. SHIRLEY. I knew him not as a doctor but as the colour sergeant of G Co. the Artists Rifles in the '90's. This company, of which I was a humble member, was composed of medical students, and I think that Charlie (as he then was) was the smartest colour sergeant in the regiment. A keen soldier and a strict disciplinarian, he was a man of great bonhomie and charm when off parade. I have very pleasant recollections of the little suppers we sometimes had in some small Soho hotel after Saturday parades. Personally I think he was cut out for a soldier and would have risen to high rank had he been in the Regular Army. The Artists want no advertisement; the value of their work and training was seen in the last war. And it was to such men as Col. Shirley that their efficiency was due; men who unselfishly gave up their leisure hours to promoting the efficiency of their famous corps.

The Services

Col. B. C. Ashton, V.H.S., I.M.S., has been appointed Honorary Surgeon to the King in succession to Major-Gen. A. A. C. McNeill, I.M.S. (ret.)

Temp. Surg. Lieut. J. F. J. Kelly, R.N.V.R., has been mentioned in dispatches for good services to the wounded in a ship which was attacked by U-boats.

Majors (temp. Lieut.-Cols.) H. J. R. Thorne and C. H. Kerr, R.A.M.C., have been awarded the D.S.O., and Capt. T. Reilly, R.A.M.C., has been awarded the M.C., in recognition of gallant and distinguished services in the Middle East.

Cpts. H. M. MacFie, W. Robinson, and J. F. Webb, R.A.M.C., have been awarded the M.C. in recognition of gallant and distinguished services in North Africa.

Brig. (temp.) E. A. Sutton, O.B.E., M.C., late R.A.M.C., has been appointed C.B.E. (Military Division), Lieut.-Col. S. W. T. Lee, Lieut.-Col. (temp.) T. F. Anderson, and Major (temp. Lieut.-Col.) D. Bell, E.A.A.M.C., have been appointed O.B.E. (Military Division), and Major A. Galloway, South African Forces (attached E.A.A.M.C.) and Lieut. (temp. Capt.) L. P. Harington, Southern Rhodesia Medical Corps, have been appointed M.B.E. (Military Division) in recognition of gallant and distinguished services in East Africa and Madagascar.

Capt. C. P. Blacker, M.C., R.A.M.C., has been awarded the George Medal in recognition of conspicuous gallantry in carrying out hazardous work in a very brave manner.

The following have been mentioned in dispatches in recognition of gallant and distinguished services in East Africa and Madagascar: Col. (temp.) B. C. O. Sheridan, M.C., Capt. (temp. Major) W. N. Hood, and Capts. G. C. Griffiths, R. H. Isaac, and W. H. Whyment, R.A.M.C.; Lieut.-Col. C. H. Marshall, Majors (temp. Lieut.-Cols.) W. K. Connell, D. D. McCarthy and C. E. Roberts, and Capt. (temp. Major) N. J. Willans, E.A.A.M.C.; Lieut.-Col. J. Wakeford and Major P. Baron, Southern Rhodesia Medical Corps.

CASUALTIES IN THE MEDICAL SERVICES

Prisoners of War.—Major R. T. Binns, A.A.M.C.; Wing Cmdr. D. Magrath, R.A.F.

The notification that Dr. N. H. R. McCallum had been mentioned in dispatches, published in a *Supplement to the London Gazette* of June 22, should have read Temp. Surg. Lieut. N. H. R. McCallum, R.N.V.R.

Universities and Colleges

UNIVERSITY OF OXFORD

In Congregation on July 1 the degrees of B.M., B.Ch. were conferred on J. A. Ritchie, and (*in absentia*) R. E. Lee.

UNIVERSITY OF LONDON

GUY'S HOSPITAL MEDICAL SCHOOL

The following awards have been made for 1943: *Entrance Scholarship in Arts*—R. Handy. *Entrance Scholarship in Science*—B. J. Silkoff.

UNIVERSITY OF BRISTOL

The following candidates have been approved at the examination indicated:

FINAL M.B., Ch.B.—J. E. Bevis, M. P. Bourke, 1 A. G. M. Davies, Mercia J. Griffiths, C. H. Gurd, Elisabeth Hodson, (Mrs.) Lois M. Leitch, D. E. Olliff, 2 Mildred J. Post, D. A. Sarsfield, 3 S. S. Short, T. R. Stephens.
1 Distinction in forensic medicine and toxicology. 2 Distinction in public health. 3 Distinction in surgery.

UNIVERSITY OF DURHAM

At a Congregation held on June 30 the University of Durham conferred the degree of D.Ch. *honoris causa* on Major-General P. H. Mitchiner, C.B.E., T.D., surgeon to St. Thomas's Hospital.

UNIVERSITY OF LIVERPOOL

The following candidates have been approved at the examinations indicated:

M.D.—A. B. Concanon, G. Sanderson, Mary D. H. Sheridan, V. K. Summers.

M.B., Ch.B.—Part III: Mary A. R. Allan, Muriel C. Andrews, A. Ansell, E. R. Banner, Beryl R. Bentley, R. A. Blyth, N. Broughton, Hilda E. Bullen, W. G. Canning, G. Davies, J. H. Foy, Joan O. Grant, E. N. Hughes-Jones, Eirwen M. Jones, J. J. Lieben, I. P. Madhok, Margaret L. Mace, A. W. Merrick, Jean C. Miller, K. H. Oldfield, E. W. Parry, E. Scott, K. H. Taggart, G. A. Weatherell. *Passed in Separate Subjects*: A. S. del (Surgery, Obstetrics and Gynaecology), H. Francis (Medicine, Obstetrics and Gynaecology), Irene W. Simpson (Medicine and Surgery), Beryl G. K. Alexander, J. T. D. Allen, E. T. Anderson, H. B. Andrews, Beryl G. 2 G. Ansell, K. W. F. Baruch, 2 J. P. D. Bates, T. J. Boag, Edith M. Brown, E. Cooper, 2 D. Craddock, Constance M. Davis, B. Dover, K. R. Dumbell, E. D. Edmondson, J. L. Edmondson, J. W. L. Edwards, R. Ellam, P. Foster, J. J. C. Frew, B. R. Frisby, S. Gillis, N. J. Gourdjii, D. A. Gregson, C. R. Helsby, 2 Winifred L. Hollick, G. Hughes, L. Jacobs, D. C. R. Jones, E. S. Jones, H. A. Jones, J. T. W. Jones, P. R. B. Jones, D. S. Jones, M. Kirwan, W. T. W. Lawson, Joyce R. Lewis, S. Lipton, B. Lynch, K. McCarthy, M. G. McEntegart, 2 R. H. Martlew, 2 Lucille F. Morgan, 2 D. B. Mossman, C. M. Ogilvie, C. A. Pearson, H. H. Pilling, J. B. Roberts, Isabel S. Smellie, G. W. Storey, P. J. Taylor, W. A. Thompson, Corris Venables, H. Wickham, J. R. E. Wilson. *Passed in Separate Subject*: A. D. Charnley, H. T. Davenport, Muriel E. St. Pier (Pharmacology and General Therapeutics).

1 Distinction in Pathology and Bacteriology. 2 Distinction in Pharmacology and General Therapeutics.

UNIVERSITY OF GLASGOW

At a graduation ceremony at Glasgow University, held on June 24, the degree of Doctor of Laws (LL.D.) was conferred on Air Marshal Sir Harold E. Whittingham, K.B.E., M.B., F.R.C.P.Lond., F.R.C.P.Ed., F.R.F.P.S., Director-General, Royal Air Force Medical Services.

UNIVERSITY OF WALES

WELSH NATIONAL SCHOOL OF MEDICINE

The following candidates have satisfied the examiners at the examinations indicated:

M.B., B.Ch.—Obstetrics and Gynaecology: S. Brest, I. F. Barwell-Clarke, Joan Collins, K. V. Crowther, 1 A. D. Evans, Eileen J. Evans, 1 H. J. Fisher, J. C. Hughes, R. G. Hughes, D. C. W. Jenkins, D. I. Jenkins, H. O. Jones, T. L. Jones, Alice M. A. Lee, Sarah M. Lewis, D. A. Macfarlane, Eiry Morgan, Mary W. Owen, E. J. Parr, J. L. J. Phillips, Winifred S. Phillips, Isabella M. Pinkerton, J. Rees-Mathews, D. B. Richards, F. W. Richards.

E. G. G. Roberts, W. Stevenson, Gertrude G. Thomas, L. P. Thomas, V. V. Tracey, H. O. Williams, Mary L. Williams, W. H. Williams. *Pharmacology*: W. H. Beasley, J. W. Bowen, B. L. Crystal, M. L. Edwards, L. A. J. Evans, M. Evans, J. C. Ham, D. W. James, W. J. Jenkins, C. G. W. Mason, J. Matthews, Isobel F. A. Mitchell, Nesta G. Morgan, Margaret Owen, D. B. Price, E. G. Rees, O. V. Rees, D. M. Rowlands, 1 R. M. E. Seal, D. R. Thomas, D. V. Thomas, G. H. Thomas, D. Tooms, Catrin M. Williams, Roberta Williams.

1 With distinction.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a meeting of Council held on July 8 Sir Alfred Webb-Johnson was re-elected President and Mr. H. S. Souttar and Sir Girdling Ball Vice-Presidents.

The following appointments were made for the ensuing year:

Hunterian Professors.—Prof. G. Grey Turner, one lecture on the Construction of the Ante-thoracic Oesophagus; Surg. Rear-Admiral G. Gordon-Taylor, one lecture on the Technique and the Results of the Surgery of Peptic Ulcer, with Special Reference to the Value of Regional and Splanchnic Anesthesia; Brig. Noel St. J. G. D. Buxton, one lecture on Gunshot Wounds of the Knee-Joint; Prof. A. B. Appleton, two lectures on the Bronchi and Blood Vessels of the Lungs; Mr. W. Sirk Adams, one lecture on the Problem of Acute Otitis Media in Children and the Response of the Infection to Sulphonamide Therapy; Surg. Cmdr. J. B. Oldham, one lecture on Coccygeal Sinus; Mr. J. F. Brailsford, one lecture on the Plasticity of Bone; Mr. T. Holmes Sellers, one lecture on Constrictive Pericarditis; Mr. T. M. Tyrrell, one lecture on the Surgery of the Lacrimal Sac; Dr. R. B. Zachary, one lecture on Factors influencing Recovery after Nerve Suture.

Arris and Gale Lectures.—Dr. N. M. Goodman, one lecture on the Supply of Subjects for Dissection: A Historical Review; Dr. Herbert Haxton, lectures on (1) the Function of the Patella, and (2) the Anatomy of Progression.

Erasmus Wilson Demonstrators.—Mr. L. E. C. Norbury, one demonstration on the pathological contents of the Museum; Mr. C. E. Shattock, one demonstration; Mr. R. Davies-Colley, two demonstrations on Certain States of Bone Absorption; Surg. Rear-Admiral Cecil P. G. Wakeley, two demonstrations on Tumours of the Alimentary Tract.

Arnott Demonstrator.—Dr. A. J. E. Cave, six demonstrations on the contents of the Museum.

Macloghlin Scholar.—Michael Hatton of Epsom College.

Diplomas

A Diploma of Fellowship was granted to A. M. L. Smith, M.B., Ch.B.

Diplomas were granted, jointly with the Royal College of Physicians of London, as follows:

DIPLOMA IN PUBLIC HEALTH.—D. Hewspear, A. S. Hoscason, Joyce B. M. Mayes, S. J. Sutton.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.—C. Anderson, H. M. Cohn, D. L. Davies, Wilhelmina L. Devlin, Elizabeth P. Dodds, H. M. James, Joan E. Mackworth, R. R. Prewer.

DIPLOMA IN LARYNGOLOGY AND OTOTOLOGY.—J. C. Liddle, P. S. Meyrick, C. P. Williams.

Medical Notes in Parliament

Food Conference at Hot Springs

In the House of Commons on July 6 Mr. EDEN made a statement on the result of the Food Conference recently held at Hot Springs. He said that the Government accepted the resolutions passed and the obligations to give effect to them in so far as they applied to conditions in the United Kingdom. They would also commend the resolutions to the Governments of the Colonies and overseas territories. The third resolution recommended that Governments should immediately begin the task of increasing food resources and improving the diets of their peoples in accordance with the principles and objectives outlined in the findings of the conference. The Government intended, despite the inevitable difficulties which the war entailed, to press on with this aim. They intended to participate fully in the work of the interim commission to be set up to prepare a plan for a permanent organization in the field of food and agriculture. One of the tasks of the commission would be to draw up a formal declaration or agreement for the consideration of the respective Governments, which would recognize their obligation towards their peoples and to one another to collaborate in raising levels of nutrition and standards of living.

In the House of Lords Lord ADDISON also called attention to the Hot Springs conference. Lord WOOLTON said that the recommendations of the conference covered the short-term and long-term phases of post-war development. The first two years after the war was bound to be a time of great stringency on the food front. We must prepare for that stringency now, as well as do what we could to meet the circumstances of the present stringencies in Europe and Asia. In the generally improved standards of nutrition and the special provision made for what the conference called "the vulnerable groups"—children, pregnant women, nursing women, and factory workers—we in this country had made really remarkable progress. Undernutrition had been vastly reduced during the war, and this was reflected in an improved national health bill. The creation of the interim commission would mean that the work of the conference would not be left in mid-air, and the Government intended to participate fully in the work of the commission.

Nurses (Scotland) Bill

Lord ALNESS, for the Government, in the House of Lords on July 7 moved the second reading of the Nurses (Scotland) Bill, which had already passed the Commons. He said one part of the Bill set up a new grade of assistant nurse, a second part restricted the use of the title "nurse," and a third established licensing and inspection of "nurses' co-operations." A period of five years had been fixed by the Secretary for Scotland for setting up the grade of assistant nurse.

The Bill was read a second time. On the following day it was taken by the House of Lords in Committee.

Lord ALNESS accepted amendments moved by Lord CRAIGMYLE to make clear that hospitals provided by the Department of Health for Scotland might be used for training assistant nurses. He said the Secretary for Scotland had communicated on the matter with the General Nursing Council for Scotland.

Lord CRAIGMYLE moved to provide that nothing in the Bill would prevent Red Cross nurses, V.A.D.s, and others now known as Red Cross nurses in Scotland from calling themselves nurses. Lord ALNESS said that, in view of the diversity in training and experience of V.A.D. nurses and nursing auxiliaries, it was impossible to promise that the regulations when made would authorize these women to call themselves nurses. Mr. Johnston would look into their claim to be so called. The amendment was withdrawn.

Lord CRAIGMYLE moved a further amendment designed to ensure that the General Nursing Council should take into consideration the training and experience gained by Red Cross, auxiliary, and assistant nurses in nursing the sick and wounded in a reputable hospital under the eyes of a fully qualified sister. He said the amendment left the General Nursing Council to decide what remission of time should be allowed to these nurses who had reached a standard of competence and training. The core of the hospital problem in Scotland was not absence of beds but shortage of nurses. Lord GEDDES said the women referred to in the relevant clause of the Bill were those who were to become State-registered nurses. In the interests of the sick he begged the House to insist that every woman on the State register of nurses had the necessary training in the fundamental sciences. V.A.D.s, if they wished, should be helped to get the training. He thought the V.A.D.s had had a "raw deal."

Lord ALNESS said the Secretary for Scotland had made a concession to assistant nurses who had at some time undergone training as student nurses. Under Lord Craigmyle's amendment any V.A.D. or auxiliary nurse who had been three weeks in a hospital might claim remission of training. The Minister of Labour and National Service was communicating with the General Nursing Councils of both Scotland and England to see whether some concession should be made in the direction proposed by Lord Craigmyle.

Lord Craigmyle's amendment was rejected by 20 to 18 and the Committee stage was completed.

Towards Cleaner Milk

On July 8 Mr. ROBERT HUDSON announced that the Government had reviewed the livestock situation in the light of prevailing trends in milk and meat production with the object of improving the quality and quantity of our milk supply. He said the basis of a sound milk policy must be a well-bred, healthy dairy herd. At present a large number of herds in the country were not inspected at all. It was proposed in future to arrange for a minimum of one inspection a year for every dairy herd and to inspect more frequently, within the limits of the available veterinary personnel, those herds with a bad disease history or where the milk was not heat-treated before sale.

To ensure the production of cleaner milk the National Milk Testing and Advisory Scheme was introduced last year. Already over 70% of the milk producers were having their milk regularly tested, while nearly 90% of the larger creameries operated the scheme. With a view to greater efficiency and uniformity in methods of milk production the Government would submit to Parliament, after consultation with local authorities in England and Wales, legislation providing for the transfer to the Ministry of Agriculture of the functions now exercised by local authorities in regard to the production of milk, including designated milk, or the farm. His Department would become responsible for all matters relating to the production of milk. Owing to transport difficulties much of the T.T. milk now produced was not sold to the public as such, but was bulked with and sold as ordinary milk. To encourage the production of this valuable milk the Government proposed to pay a uniform production premium of 4d. a gallon. The Minister of Food would take all practicable steps to ensure

that as much T.T. milk as possible in present circumstances was sold as such to consumers. The price would be only slightly higher than for ordinary milk. Schemes introduced by the Ministry of Food for the rationalization of the retail distribution of milk deprived the public in areas to which such schemes applied of their freedom to choose their milk suppliers. In some cases persons who previously made a point of buying pasteurized or T.T. milk now received ordinary raw untreated milk. This placed upon the Government the obligation to ensure, as soon as possible, that all milk supplied to consumers in areas affected by rationalization schemes should conform to the higher standards of purity previously demanded. The Government's intention was to prohibit, in areas to be scheduled, the retail sale of milk unless it was (a) T.T. milk; (b) accredited milk sold by a retailer who sold the milk of a single accredited herd; or (c) milk which had been rendered safe by means of heat treatment. This policy would be applied, in all areas affected by schemes for the rationalization of retail distribution, as rapidly as the necessary plant could be made available.

A White Paper was published on July 8 which gave Mr. Hudson's proposals in greater detail and set out a parallel scheme for Scotland. In that country it is not proposed to take from local authorities the powers they possess over milk supplies.

Comprehensive Health Service

Mr. ERNEST BROWN told Lady Apsley on July 8 that in connexion with the discussions for a comprehensive health service, he hoped fairly soon to issue a general statement which might serve as a focus for the views of all interested bodies. He had undertaken at that stage to get into touch with the Associations of Medical Aid Societies.

Alien Doctors in Hospitals

In answer to Sir Robert Young on July 8 Mr. ERNEST BROWN said the number of doctors of Allied and neutral countries employed as such in hospitals was 200. The number of specialists included in this total was not available. An over-sea doctor could acquire a British medical qualification by passing one of the qualifying examinations after the appropriate period of study. He could also be placed temporarily on the British Medical Register if the General Medical Council was satisfied that he fulfilled certain prescribed conditions as to the holding of medical diplomas and otherwise. Mr. Brown added that his approval was not required for the qualification or registration of an individual doctor.

Higher Education and Research in the Colonies

In the House of Commons on July 13 Colonel OLIVER STANLEY gave a comprehensive review of the progress made in colonial affairs and of the plans for the future. He said that educational advance and economic development were the twin pillars on which any sound scheme of political responsibility must be based. With regard to higher education, it was quite clear that if our goal of colonial self-government was to be achieved colonial universities and colleges would have to play an immense part. They would have to meet the enormously increased need for trained professionals which increased social and economic services would necessitate. They would have to provide the agriculturists, engineers, doctors, teachers, veterinary surgeons, and specialists and technicians which the approach to higher standards of life would entail. They would have to do an immense amount of research. In encouraging the constructive growth of these universities and colleges, the guidance and help of the home universities must be looked for. It would be a tremendous gain if, in a way, the colonial colleges could be admitted as partners in the circle of the home universities, and if there could be an intellectual Lend-Lease between the universities here and the colonial centres of higher education. He believed that the practical difficulties, which were many, could be overcome. He was accordingly setting up a Commission of Inquiry, with Mr. Justice Asquith as chairman, to inquire into the general problem of the relationship between home and colonial universities, and the way in which the latter could best be assisted. He was also setting up a Commission of Inquiry into higher education in British West Africa, of which Dr. Walter Elliot would be chairman, and on which three African representatives had been invited to serve.

Col. Stanley added that with regard to primary education the whole question of reducing mass illiteracy was now being considered by his Advisory Committee on Education, and he hoped shortly to receive its report. The Minister said that our objective in the Colonial Empire must be to make the Colonies self-supporting.

Medical News

Dr. A. J. Amor has been appointed Chief Medical Officer of the Ministry of Supply with effect from July 19, in succession to Air Vice-Marshal Sir David Munro, who has relinquished that appointment. Sir David Munro has been appointed Medical Adviser to the Ministry with effect from the same date.

The Distinguished Service Medal and Award of the American Medical Association for 1943 has been conferred on Dr. Elliott Proctor Joslin, whose outstanding work on diabetes is recorded in the *Journal of the American Medical Association*.

The President of Poland has conferred the Order of Polonia Restituta, Third Class, on Prof. Sydney A. Smith, M.D., Dean of the Faculty of Medicine, University of Edinburgh, and Prof. F. A. E. Crew, M.D., F.R.S., in recognition of services during the war.

After the annual general meeting of the Medical Society for the Study of Venereal Diseases to be held at 11, Chandos Street, Cavendish Square, W., to-day (Saturday, July 24), a medical meeting will begin at 2.30 p.m., when papers will be read on hyperthermia in the treatment of resistant gonococcal and non-specific urethritis, and on physiological changes in fever treatment.

On July 21 the Minister of Agriculture attended the centenary commemoration of the founding of the Rothamsted Experimental Station, Harpenden, when the laboratories, field experiments, and the 100th wheat crop on Broadbalk Field were inspected at the invitation of the Lawes Agricultural Trust Committee, of which the Earl of Radnor is chairman.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* during the week there were 304 more notifications of scarlet fever and 26 more of diphtheria, but there were 1,609 fewer cases of measles and 81 fewer of whooping-cough.

Only small changes in the trend of diphtheria within the counties were reported. The largest variations in the totals for scarlet fever were rises in Yorks West Riding 35, Lancashire 33, and Essex 31. The greatest rises in whooping-cough were in the counties of Southampton 35, Durham 32, Warwick 31. The largest falls in the notifications of measles were Staffordshire 155, Lancashire 148, Norfolk 140, London 118.

The notifications of dysentery rose from 13 to 120. The only new outbreak was in Leicestershire, Hinkley U.D. 10; 14 more cases were reported from the outbreak in Bristol C.B.; the only other large centre of infection was London, with 20 cases in ten boroughs.

In *Scotland* the notifications of infectious diseases fell substantially: whooping-cough by 107, measles by 88, dysentery 44, and scarlet fever by 43; but diphtheria was up by 15. The reduction of whooping-cough was due to a fall of 103 in Glasgow. Glasgow, with 98 fewer cases of measles, was also responsible for the downward trend of this disease, the outbreaks in Edinburgh and Dundee remaining at a constant level. In Paisley the cases increased by 37. The number of cases of cerebrospinal fever has been fairly constant for the whole country during the past five weeks, but there has been a slight drop in Glasgow, where 19 of the 30 cases occurring during the week were recorded.

Quarterly Return for England and Wales

The birth rate during the first quarter of this year was 16.8 per 1,000, the highest rate for a first quarter since 1928, and was 2.0 above the average for the five preceding March quarters. The sex rates of births were 1,070 males to 1,000 females, compared with an average for the ten preceding first quarters of 1,058. The infant mortality was 60 per 1,000 live births—14 below the average of the ten preceding first quarters. The rate for stillbirths was 33 per 1,000 of the total births registered. The general death rate was 13.5 per 1,000, compared with an average of 16.5 for the five preceding first quarters. The natural increase—excess of births over deaths—was 34,251. In the March quarter of 1942 the increase was 6,963, while in the first quarters of 1940 and 1941 the births were in defect of the deaths by 50,838 and 31,610.

The number of persons marrying was 124,674. This was 51,770 fewer than in the first quarter of 1942, and was the lowest number in any quarter since the outbreak of war.

The Week Ending July 10

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,959, whooping-cough 2,284, diphtheria 580, measles 3,593, acute pneumonia 502, cerebrospinal fever 49, dysentery 93, paratyphoid 12, typhoid 8.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended July 3.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

† Includes puerperal fever for England and Wales and Eire.

‡ Owing to evacuation schemes and other movements of population, birth death rates for Northern Ireland are no longer available.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON W.C.1.

ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Secretary of the Journal Board, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. If reprints are required, as proofs are sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be sent to the Secretary.

TELEPHONE No.—B.M.A. and B.M.J.: EUSTON 2111.

TELEGRAPHIC ADDRESSES—EDITOR, *Aitology Western, London*; SECRETARY, *Medisera Western, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

ANY QUESTIONS?

Primary Vaccination of Adolescents

Q.—I have been asked to vaccinate a previously unvaccinated girl aged 12 years, as she is being sent to a boarding school, the head master requiring such vaccination before her admission. (1) Is such a primary vaccination either safe or desirable in the absence of a small-pox epidemic? (2) What is the dosage of lymph for intra- or sub-cutaneous vaccination, and do such methods leave a scar?

A.—1. The Ministry of Health deprecates the imposition of vaccination as a condition of admission to an institution or of employment in this country. The vaccination of persons of adolescent or school age who have not been previously vaccinated is not desirable unless they have been in contact with a case of small-pox or have been directly exposed to small-pox infection.

2. It is customary to use 0.1 c.cm. of 1:50 to 1:200 dilution of lymph—i.e., of vaccinal pulp after its dilution with glycerin water 1 in 5 or 6; but we do not know the amount of vaccinia virus in the pulp. This necessarily varies with the time and method of collection, and there is no method of ascertaining the virus content. There is no scar formation (unless there is accidental vesicle formation), and in this connexion Henderson and McClean (*J. Hyg., Camb.*, 1939, 39, 680) noted that unless there was vesicle formation there was little immunity. These authors found a definite correlation between the appearance of a typical epidermal vesicle and the subsequent development of immunity. It is to be borne in mind that calf lymph is not sterile, and the possible danger of introducing adventitious organisms into or under the skin should be considered. In some cases persistent induration is said to follow.

Streptococci and Nephritis

Q.—Will a chronic streptococcal infection of the throat cause high blood pressure by insidiously damaging the kidneys?

A.—So far as is known, streptococcal infections of the throat only cause high blood pressure through the medium of nephritis, in which condition albumin is rarely absent from the urine, and red cells and casts are usually present also when the spun deposit of a fresh specimen is examined. Wintenwerder *et al.* (*Arch. intern. Med.*, 1935, 56, 297) have found that the persistence of streptococci in the nasopharynx is commoner in nephritic patients in whom the condition is progressive than in those who recover, but operations to remove infected foci produced neither disappearance of the organisms nor amelioration of the nephritis. It is not yet clear whether nephritis is the result of a reaction between streptococcal antigens and antibodies, or due to a different agent such as a virus.

High Blood Pressure in Pregnancy

Q.—What is considered high blood pressure in pregnancy, especially in the last month, in the absence of clinical signs of renal affection? What does it signify? I have a patient aged 23 years in her last month of pregnancy, with no evidence of renal trouble, but her blood pressure is 170/80. I have read somewhere that this may bring on premature labour.

A.—It is generally accepted that at any stage in pregnancy a systolic pressure of over 140 or a diastolic pressure of over 80 is pathological. Some authorities even put the limits of normal at 130 and 70. In the absence of evidence of nephritis the raised blood pressure is indicative of either essential hypertension or of pre-eclamptic toxæmia. In the case of essential hypertension the blood pressure is raised throughout pregnancy with a tendency to exacerbation in the later weeks. In pre-eclampsia the rise of blood pressure does not usually occur until the last one or two months of pregnancy, but may precede other signs such as albuminuria and oedema. Patients suffering from essential hypertension are more likely to develop pre-eclampsia or eclampsia; so whichever is its cause the raised blood pressure in this particular case should be

regarded as being of serious significance. Premature onset of labour is one of the common complications of the toxæmias of pregnancy, but there is no direct connexion between a rise in blood pressure and the onset of labour.

Deafness after Scarlet Fever

Q.—A patient, partially deaf since childhood (due to scarlet fever), recently had a severe catarrhal cold with subsequent copious mucopurulent discharge from the nose. When this got better his hearing considerably improved, and in fact has been better than it has been for two years. He is now aged 54. Is there any remedy that would keep his hearing fairly normal? At present I think it is about 80% normal, whereas for a considerable time past it has hardly been 40%. Eustachian inflation has done no good.

A.—Unless accurate observations with an audiometer were made of this patient's hearing it is not possible to form any valid conclusions. The late Dr. Albert Gray, however, observed that in a few cases of otosclerosis a coryza caused a temporary improvement in hearing, which was attributed to an increase in the blood supply from vasodilatation. Possibly a cervical sympathectomy might have the same effect, but it would be too experimental to be seriously considered.

Cows, Rheumatism, and Streptococci

Q.—Do cows suffer from rheumatic arthritis and endocarditis? If so, that would explain where the infection of acute rheumatism comes from.

A.—Cows do not suffer from rheumatic arthritis and endocarditis: there is in fact no animal naturally subject to rheumatic fever as seen in man, though various other forms of arthritis are common among them. The insusceptibility of animals is actually an obstacle to the experimental study of rheumatic fever. There are, however, strong reasons for regarding infection, primarily involving the throat, by haemolytic streptococci as an essential part of rheumatic fever, if not its whole cause. The cow or its milk is thus involved to the extent that in some cases they may be the source of the infection. Streptococcal mastitis in cows is occasionally due to infection of human origin, the streptococcus being of Group A, and thus liable to produce serious disease in man: more commonly it is of Group B (*Streptococcus agalactiae*), which is much less pathogenic to man. Alternatively, milk may be directly contaminated by cough spray or otherwise from a human source. This ever-present danger constitutes one of the many reasons why general pasteurization of milk is necessary in the interests of the public health.

Jaundice after Serum Injection

Q.—Is the jaundice following the injection of measles serum and other sera (homologous serum jaundice) due to the lighting up of a dormant virus?

A.—There is, as yet, no evidence that homologous serum jaundice is due to a virus. It has been assumed by many workers that this condition is due to the virus of infective hepatitis (epidemic catarrhal jaundice). It should be noted, however, that the incubation period of the two conditions is different: 2 to 3 months in homologous serum jaundice and round about 1 month in infective hepatitis. Perhaps one should not have used the term "incubation period" for the former condition, since there is no real evidence that it is an infective process. It may be, but that remains to be established. Two additional points make one hesitate to accept the view that homologous serum jaundice is due to the virus of infective hepatitis. It is assumed that certain batches of serum are iatrogenic because they come from donors who happened to have this virus in the circulation when they were bled; yet it is strange that no well-established case exists of jaundice following transfusion with whole blood. The second point is the absence of well-authenticated secondary cases arising as the result of exposure to a case of serum jaundice. Future investigations should be made with a view to an unequivocal answer to these two points.

Oestrogens for Small Breasts

Q.—One of my patients, a multip-2, has small, rather shrunken breasts, of which she complains for cosmetic reasons. She is otherwise well developed. Oestradiol injections have proved useful for undeveloped virgin breasts. Would they achieve anything in a case of this nature? What dosage should be employed? "Progyon" ointment contains 0.1 mg. of hormone in 1 g. of base. What is the strength in i.b.u.? Are there likely to be any ill effects from the continued use of oestradiol, and is the susceptibility to conception increased?

A.—Incomplete development of virgin breasts is due to the relatively low concentration of oestrogen secretion in the adolescent girl. Small shrunken breasts in a multip-2 without other evidence of oestrogenic deficiency indicate a peripheral resistance on the part of the breasts to the normal ovarian activity rather than a lack of intrinsic oestrogen. Such local insensitivity is often very obstinate and is unlikely to be overcome by extrinsic oestrogen administration.

It is improbable, therefore, that oestradiol injections would achieve any spectacular result in such a case. Dosage is still rather arbitrary. Oestrogen ointments containing 2 mg. per g. are available, and the higher dose should be preferred, though there is evidence that local application is more effective in such conditions than an equivalent dose given either by the oral or parenteral route. 0.1 mg. is equivalent to 1,000 i.b.u. Continued use of oestrogens is to be deprecated. The most likely ill effect is disturbance of menstruation as evidenced either by temporary suppression of menstrual bleeding if the dose is sufficiently effective or excessive uterine haemorrhage with a less effective dose.

Inhibition of pituitary function may result from continued high dosage of oestrogen, though this is usually seen only in cases of obvious pituitary over-activity. For instance, high-dosage oestrogen therapy is temporarily of benefit in cases of Cushing's syndrome (pituitary basophilism) and acromegaly (pituitary eosinophilism). The carcinogenic tendencies which may result from continued administration of oestrogen have been frequently cited by certain clinicians. Though consideration of the pertinent animal experiments is reassuring on this point, it would be foolish to suppose that administration of, say, 1 mg. of oestrogen daily for a period of 3 years would be without risk. If the susceptibility to conception were to be affected at all it would be diminished. Though oestrogen could in no manner be described as a contraceptive, continued high dosage would tend to inhibit the luteal (or secretory) phase of the menstrual cycle and would therefore not favour conception.

Some Drug Conundrums

Q.—A patient of mine has been taking a preparation of potassium iodide 9.25%, caffeine 1.32%, and sod. benz. 1.85% for about two years. He apparently stood this preparation well until about a month ago, when he came out in an iodide rash. On my advice he stopped taking it, and he found that he became very short of breath, especially on exertion, and in fact has had to go back to the preparation and gradually reduce the dose; but he is not able to give it up altogether. He suffers from bronchial trouble with emphysema; no real asthma. Thinking there was probably an adrenal deficiency through the caffeine, I put him on tablets made up of suprarenal extract gr. 1/2, thyroid gr. 1/12, orchic substance gr. 2; but this does not seem to have had much effect. I have also suggested inhalations of 1 in 100 adrenaline when the dyspnoea became pronounced.

A.—The effective element in the first preparation is probably the potassium iodide. The development of intolerance in this way is unfortunately not unusual; it may be to some extent alleviated by intermitting the drug for a time. The expectorant action of the iodide might be duplicated by ammonium chloride gr. 5 t.d.s., or apomorphine hydrochloride gr. 1/32, or a combination of the two. The only active agent in the second preparation is the thyroid, as neither suprarenal nor testicular hormones are absorbed in this dosage by mouth. In any event there is no evidence that patients with asthma or emphysema suffer from adrenal exhaustion, which appears to be a mythical malady invented by the advertising agents. In experimental animals denervation of the adrenals or even complete sympathectomy does not lead to notable functional disturbances under normal environmental conditions. If the patient complains of exhaustion, it may well be due to the withdrawal of the caffeine, which is a cerebral stimulant. The caffeine and sodium benzoate might therefore be given alone or be replaced by another xanthine derivative—theophyllin with ethylene diamine, gr. 1½ to 3 t.d.s. Otherwise an attempt may be made to replace the drug with either amphetamine sulphate or methedrine, 2 to 4 mg. at breakfast and noon; or ephedrine hydrochloride gr. 1/2 with phenobarbitone gr. 1/2 p.r.n., up to thrice in the day. Finally, the value of respiratory exercises is worth stressing, particularly in a case of this kind, in which there may be a considerable fraction of neurasthenia.

Premature Greying of Hair

Q.—Is there any treatment which holds out hope of a cure for premature grey hair?

A.—Following the observation that pantothenic acid and p-aminobenzoic acid are necessary for normal pigmentation of the hair of the rat, which becomes grey in their absence from the diet, attempts have been made to treat premature greyness in human beings with these substances. Success has been claimed for the treatment of such cases with vitamin B complex preparations and with p-aminobenzoic acid (*Science*, 1941, 94, 257) in conjunction with endocrine products (thyroid). The dosage of p-aminobenzoic acid was 100 mg. twice daily by mouth. After about two months' treatment darkening of the hair was reported. The calcium salt of pantothenic acid has been tried in doses of 100 to 500 mg. twice weekly intramuscularly, but appears to be ineffective (*Amer. J. digest. Dis.*, 1943, 10, 45). If p-aminobenzoic acid is used it must be discontinued if sulphonamides are ever given. Of suitable vitamin B complex preparations yeast is the cheapest.

Premature loss of the colour of the hair is occasionally a manifestation of endocrine disorder, and particularly is this so in Simmonds's cachexia (hypopituitarism), but the hair changes are usually associated with other endocrine features. It is well known that a sudden shock may cause a greying or whitening of the hair, but it is less well known that a sudden shock may be followed by the syndrome of Simmonds's cachexia, probably via the hypothalamic-pituitary mechanism. About the treatment of this condition little is known from an endocrine point of view, but in one case of incomplete Simmonds's cachexia following parturition, in which the hair tended to lose its colour and become dry and brittle, the administration of testosterone produced a return of colour, lustre, and silky appearance. Such therapy should be used with caution in a female. Thyroid extract and oestrogens have also been advocated in this condition.

LETTERS, NOTES, ETC.

Vitamin E and Other Standards

Dr. PERCIVAL HARTLEY, F.R.S., Director of Biological Standards, National Institute for Medical Research, Hampstead, N.W.3, writes: In the *Journal* of July 10 (p. 61) under "Any Questions?" it is stated that there is no international unit for vitamin E. The circumstances under which an international standard, and an international unit defined in terms thereof, for vitamin E have been established and provided for international use are explained in the *Journal* of Oct. 18, 1941 (p. 553). Briefly stated, the international standard for vitamin E is a specimen of α -tocopheryl acetate, and the international unit is defined as the specific biological activity contained in 1 milligramme of the standard preparation. This opportunity is taken of reminding research workers and those laboratories and institutes in any part of the world who require international biological standards for their work that, on behalf of the Health Organization of the League of Nations, the international standards for drugs, vitamins, and hormones, and for antitoxins, antisera, and tuberculin (thirty standards in all established since 1922 by the League) are maintained at this Institute and will be supplied on application, free of charge, to the Directors of National Control Centres in those countries in which these have been established, or directly from this Institute to individual workers and others situated in countries in which such centres are not yet in operation (see *Journal*, July 6, 1940, p. 24).

"Morton's Metatarsalgia"

Mr. W. SAYLE CREER (Manchester) writes: In the section "Any Questions?" (June 26, p. 808) there is a short note relating to "Morton's metatarsalgia." It is, I fear, very inaccurate, as are most accounts of the condition. Your writer says: "Morton's metatarsalgia is not a diagnosis." He does not say what it is. Now "metatarsalgia" means pain—in the same way as neuralgia, neuritis, and sciatica mean certain pains—in the region of the metatarsal heads. The word denotes a symptom and not a diagnosis. But "Morton's metatarsalgia" does denote a diagnosis—a particular variety of metatarsalgia. It denotes pain of an intermittent, excruciating nature shooting into the second, third, or fourth toe. It was first described in 1875 by Prof. D. P. (or T. G.—various books give different initials) Morton, and attributed by him to pressure on a digital nerve by, at, or near one of the metatarsal heads. D. J. Morton says it is due to arthritis of a metatarsophalangeal joint. It is a distinct, though rare, cause of pain in the forefoot. Prof. Morton was wrong in attributing it to pressure on digital nerves, just as Dr. D. J. Morton is incorrect in ascribing it to arthritis of the metatarsophalangeal joint. The latter is a much more frequent condition with a distinctly different type of pain—stabbing, yes, but shooting, no. One always hesitates to say anything is impossible in surgery, or medicine, yet there is no other course left when considering the possibility of normal digital nerves being pinched by normal metatarsal heads. With a metatarsal head increased in size by osteophytes, as occurs in the condition called "Kohler II," pinching is theoretically possible. I haven't seen it yet. Morton's metatarsalgia occurs with normal metatarsals; only when there is a fibromatous or neurofibromatous enlargement of the digital nerve. But it is so rare that in fourteen years I have been tempted to operate only once; the enlargement was there. Excision cured the disease. I know of only three other cases. None has been published yet.

Disclaimer

Dr. A. GUIRDHAM writes: A pamphlet entitled *Revolt against Pity*, written by me, contains on its title-page several decorative additions, including references to periodicals, medical and other wise, to which I have contributed. The form of this title-page was made without my being consulted, and the proofs were not submitted to me before publication, though the agreement signed with the publishers specifically indicated that this would be so. This pamphlet is non-medical and related to the present crisis. Nevertheless I would be glad if you would publish my objection to the above-mentioned additions to my name on its title-page.

LONDON SATURDAY JULY 31 1943

TYPING OF PARATYPHOID B BACILLI BY MEANS OF VI BACTERIOPHAGE*

BY

A. FELIX, D.Sc., F.R.S. AND BESSIE R. CALLOW, M.A.

(From the Emergency Public Health Laboratory Service)

An account was given in a previous paper (Felix, 1943) of experience with the bacteriophage typing of typhoid bacilli according to the technique of Craigie and Yen (1938a, 1938b). The conclusion reached was that the method is an indispensable laboratory aid to the control of typhoid fever. In this country during the past few years paratyphoid B fever has been much more prevalent than typhoid fever. It appeared, therefore, highly desirable to investigate the possibility of applying Vi-bacteriophage action to the examination of paratyphoid B cases and carriers.

The presence in cultures of *Bact. paratyphosum* B of an antigen resembling the typhoid Vi antigen was described some years ago (Felix and Pitt, 1936), but most workers paid little attention to this finding. Kauffmann (1936a, 1936b) attempted to identify the antigen with one of the several components of the complex O antigen assigned to the paratyphoid B bacillus in the Salmonella scheme of Kauffmann and White (Salmonella Subcommittee, 1934). The intricacies of this controversial problem cannot be discussed here, but it may be stated that unpublished experiments carried out by one of us (A.F.) in collaboration with Miss R. M. Pitt before the war strongly indicated that paratyphoid B bacilli possess a heat-labile somatic antigen that is essentially similar to the typhoid Vi antigen, though differing from it in certain respects. Moreover, experience during the present war confirms the earlier observation, and every paratyphoid B strain isolated in this country which has been examined up to the present time contains the heat-labile "Vi" antigen.

These facts are the theoretical basis of the present investigation. The data from the bacteriological and serological experiments will be published elsewhere; only those results are summarized here which help to make clear the practical application of the method.

Isolation of Anti-Vi and Anti-O Bacteriophages

During 1941 large outbreaks of paratyphoid B fever occurred in different parts of the country, and, thanks to the co-operation of many pathologists, nearly 500 cultures of the paratyphoid B bacillus were collected and examined within a few months. Bacteriophages were grown from specimens of faeces of paratyphoid B patients, convalescents, and carriers; from freshly isolated "smooth" cultures that were found to be phage-contaminated; and from "rough" variants of paratyphoid B strains; a few bacteriophages were also received from Dr. R. Knox of the E.P.H. Laboratory, Leicester. It was soon found that most of the phages obtained from these sources were anti-O phages that acted on paratyphoid B bacilli as well as on *Bact. typhi-murium* bacilli and many other members of the Salmonella group. Even minor O-antigenic components that are common to the various Salmonella species, though they are not listed in the Kauffmann-White diagnostic scheme, provide an adequate point of attack for anti-O bacteriophages.

On the other hand, a number of phages were found which were specific for the paratyphoid B bacillus. These phages

did not attack any of the other Salmonella species tested, and were therefore considered to be specific anti-Vi paratyphoid B phages. They differed, however, in one respect from the corresponding typhoid Vi phages described by Sertic and Boulgakov (1936), Scholtens (1936), and Craigie and Brandon (1936). The typhoid Vi phages, when employed in the form of concentrated unadapted preparations, attack every strain, or almost every strain, of the typhoid bacillus, so long as the bacilli contain enough of the Vi antigen to provide the required point of attack. Our Vi paratyphoid B phages, however, acted selectively on certain paratyphoid B strains but failed to lyse other strains, in spite of the fact that these also contained the heat-labile somatic Vi antigen.

It is noteworthy that the non-specific O phages were grown readily from specimens of faeces, whereas the specific Vi phages could be isolated only exceptionally from this source. Thus, of the first ten anti-O phages examined seven were derived directly from faecal specimens and three were isolated during the process of purification of Vi phages, which was in each instance carried out by repeated transplantation from single plaques. On the other hand, the first ten anti-Vi phages were obtained from the following sources: five from lysogenic "rough" variants, four from phage-contaminated "smooth" cultures of the paratyphoid B bacillus, and only one direct from a specimen of faeces.

Although the Vi bacteriophages had been isolated from patients in localities as widely separated as Aberdeen and Inverness in the north, and Bristol and Exeter in the south, no difference in their affinities for different paratyphoid B strains could be detected. Every strain examined was either lysed by all the Vi phages or was resistant to all of them, no matter in which part of the country the strain had been isolated. All the strains examined during any given outbreak usually behaved in a precisely similar manner towards all the available Vi phages: this was interpreted as indicating that the cases had a common source of infection. Such confirmation by laboratory findings, though of limited value, was appreciated by the medical officers of health who were investigating the outbreaks (Davies, Cooper, and Fleming, 1942; Parry, 1942). There seemed, however, at that time to be little hope of attaining our goal—namely, the differentiation of paratyphoid B strains into a number of distinct Vi-phage types. As was proved later, nearly all the larger outbreaks during 1941 were due to strains belonging to the same bacteriophage type—namely, Type 1 (see Table III).

Adaptation of Vi Bacteriophages

The position at once changed when the first instance of adaptation of a Vi phage had been observed. This occurred in the course of the examination of cultures from a relatively small outbreak of paratyphoid B fever in Ipswich during July-Aug., 1941. Thanks to the most helpful co-operation of Dr. P. H. Martin of the E.P.H. Laboratory, Ipswich, we were able to examine the strains from all the patients concerned and also from a number of cases that occurred at the same time elsewhere in East Suffolk. The "Suffolk" strains were all lysed by the available Vi phages in very high dilutions, exceeding in some instances even a dilution of 1 in 10 millions, whereas the "Ipswich" strains were all insusceptible. When

* A report to the Medical Research Council.

however, certain of the phage preparations were applied in a concentration about a million times stronger than the usual amount a few plaques were occasionally produced on some of the "Ipswich" strains. New preparations of bacteriophage grown from these plaques still lysed the "Suffolk" strains, but they also lysed the "Ipswich" strains to the same titre. Using one of the original Vi phages, which had been isolated from a patient in Aberdeen, and the new preparation derived from the "Aberdeen" phage and adapted to the "Ipswich" strains, we were now able to identify every strain that belonged to the "Ipswich" type.

The next Vi phage to be specifically adapted to certain strains was obtained by an analogous procedure during the examination of strains from a small outbreak in Southampton. The cultures had been isolated by Dr. J. T. Duncan of the E.P.H. Laboratory, Winchester, during May-June, 1940, and were found to be resistant to all the original Vi phages, including the "Aberdeen" phage and the adapted "Ipswich" phage. After numerous unsuccessful attempts a few plaques were eventually produced by the adapted "Ipswich" phage on some of the Southampton strains, and from these plaques another adapted phage was initiated. The new phage preparation possessed a strong lytic power for all the cultures from the Southampton outbreak, but had entirely lost the lytic power for the "Ipswich" strains which it had acquired during the previous process of adaptation. Its affinity for the parent strain ("Aberdeen" strain) still remained unchanged. The original "Aberdeen" Vi phage was now labelled "Type 1," and the adapted "Ipswich" and "Southampton" phages were designated as "Type 2" and "Type 3" respectively.

TABLE I.—Showing the Reactions of Type Strains of *Bact. paratyphosum* B and *Bact. typhi-murium* to Anti-Vi and Anti-O Bacteriophages

Type Strains	Anti-gens Present in the Strains	Anti-Vi Bacteriophages				Anti-O Bacteriophage	
		Bact. paratyphosum B					
		Type 1	Type 2	Type 3a	Type 3b		
lact. para-typhosum B	Type 1 ..	Vi+O	CL	CL	+++	-	CL
	" 2 ..	Vi+O	-	CL	-	-	CL
	" 3a ..	Vi+O	-	-	CL	-	CL
	" 3b ..	Vi+O	-	-	SCL	-	CL
	Untypable (Group Z)	Vi+O	-	-	SCL	-	CL
Bact. typhimurium	Type 1 ..	Vi+O	-	-	-	CL	CL
	Vi-negative variant	O	-	-	-	-	CL

CL=Confluent lysis with standard loopful of test dilution of phage.
SCL=Semi-confluent lysis with standard loopful of test dilution of phage.
+++=Numerous discrete plaques, subnormal in size.

So far only four different Vi-phage types of *Bact. paratyphosum* B have been identified; their relationship to each other is indicated in Table I. Type 1 strains are lysed by all the available BVi* phages, whereas the other three types are attacked only by the corresponding adapted BVi phages. Group Z is the provisional designation chosen for the untypable strains that are resistant to all the BVi phages so far available in spite of the fact that the cultures contain the BVi antigen. There can be little doubt that this group comprises a number of further Vi-phage types that have not been identified because the corresponding type phages have not yet been isolated.

If the typing scheme outlined in Table I is compared with that at which was first devised by Craigie and Yen (1938a) for the typing of the typhoid bacillus it is seen that the two are very similar, and indeed almost identical. The first place in each of the two schemes has been assigned to the type of bacillus that is sensitive to all the adapted phage preparations; the phages corresponding to these types—namely, Type A phage of the typhoid bacillus and Type 1 phage of the paratyphoid B bacillus—nevertheless possess a high degree of specificity. The remaining types in the two schemes are all characterized by their particular sensitiveness to the homologous adapted type phage. The relationship between subtypes of the paratyphoid B bacillus (Types 3a and 3b) is also similar to that obtaining between the various subtypes of the typhoid bacillus.

* The symbol BVi is used throughout this paper to denote the Vi antigen of the paratyphoid B bacillus.

Bacteriophages adapted to Types 2, 3a, and 3b were isolated many times later in the course of this investigation. The phage preparations were obtained as the result of cross-reactions between cultures and Vi phages that had been derived from outbreaks or sporadic cases in various parts of the country. Whichever of these phage preparations were employed in the typing of paratyphoid B strains, the results obtained were invariably the same—namely, identical with those summarized in Table I.

The table also shows that *Bact. typhi-murium*, which shares the heat-labile Vi antigen with *Bact. paratyphosum* (Felix and Pitt, 1936), is not lysed by any of the four BVi type phages. *Bact. typhi-murium* is sensitive to its own specific Vi phages, of which two different types have been identified so far. Table I shows only one of these. It remains to be investigated whether the specificity of these phages is as strict as it appears to be at the present time.

The procedures that led to the adaptation of anti-Vi phages were also applied to the examination of a number of anti-O phages. In no instance, however, did we succeed in training an anti-O phage to develop strain specificity. This finding is of great interest, from the theoretical point of view, since it provides additional evidence of the similarity between the Vi antigen of typhoid and that of paratyphoid B bacilli. Table I shows that an anti-O phage attacks strains belonging to all known Vi-phage types of the paratyphoid B bacillus and also Vi-positive and Vi-negative strains of *Bact. typhi-murium*.

The Epidemiological Significance of Paratyphoid-B Vi-phage Types

It has already been mentioned that the subdivision of paratyphoid B strains into Vi-phage types first proved its usefulness during a small outbreak in Ipswich, July-Aug., 1941, which was examined bacteriologically by Dr. P. H. Martin. The epidemiology of this outbreak has been very thoroughly investigated by the Ministry of Health, in co-operation with the E.P.H.L. Service, and a report by Dr. J. R. Hutchinson appears on page 130 of the present issue (Hutchinson, 1942). The clear-cut result of the field inquiry was that all the cases from which Type 2 bacilli had been isolated had a common source of infection, whereas the cases that were due to Type 1 bacilli were unrelated to that source.

Many outbreaks, large and small, have been investigated since, and our experience so far has been that the epidemiological significance of paratyphoid-B Vi-phage types is much the same as that of the now well-established typhoid Vi types. A few instances may be mentioned here by way of illustration. During the paratyphoid B outbreak in Liverpool, May-September 1941 (Holt, Vaughan, and Wright, 1942), 72 cultures, derived from 66 patients or temporary excretors, were examined. The included cultures isolated from three employees of the bakery responsible for the outbreak and from a synthetic cream used by the firm in question. All these cultures were found to belong to Type 1. In an outbreak in Bristol, July-Oct., 1941 (Davies, Cooper, and Fleming, 1942), five strains from the primary wave in August and six strains from the secondary wave in September were typed, and it was found that again all the cultures were of Type 1. On the other hand, thirty strains from the outbreak in Consett, June, 1940 (Warre, 1941), and six strains from the 1939 outbreak in Bebington (Hughes and Harwood, 1940) were typed, and all were found to belong to Type 3a.

Several chronic faecal carriers of *Bact. paratyphosum* B have been examined repeatedly over periods varying from a year to over three years. The phage type of the excreted organisms in every instance remained unchanged during the period of observation. These results permit us to state with confidence that the typing of paratyphoid B bacilli by the Vi-phage technique is a reliable aid to the epidemiological investigation of cases or outbreaks of the disease.

Paratyphoid-B Vi-phage Types Prevalent in England, Wales and Scotland during 1940-2

The results so far obtained with the typing of strains of the paratyphoid B bacillus have been summarized in Tables II and III. The number of cultures examined in the course of this investigation was 808, including about 100 cultures from the late W. M. Scott's collection; the number of patients a

carriers, temporary or chronic, from whom the cultures had been derived was 714. Many paratyphoid B outbreaks of considerable size occurred in the British Isles during 1941, and nearly all of these were due to Type 1 bacilli. As a sequence to these outbreaks, cultures of Type 1 strains from convalescent patients and temporary excretors continued to be sent in for examination throughout the following winter and well into the first quarter of 1942. It seemed advisable, therefore, to choose March 31, 1942, as the date separating the "epidemic" year 1941 from the "non-epidemic" period that followed it. The distribution of the various types during the three years under observation can thus be traced more accurately than by strictly adhering to yearly periods.

TABLE II.—Showing the Vi-phage Types of *Bact. paratyphosum* B found in England, Wales, and Scotland during April, 1940, to March, 1943

Total typhoid and paratyphoid fevers	1,322	1,479	2,833	1,145	3,618	868

In order to assess the significance of the figures shown in Part I of Table II it is necessary to emphasize that the method of collecting the cultures for typing has not been the same throughout the whole period under review. During the initial stages of the investigation it was felt that no useful information could be obtained from the examination of sporadic cases or small groups of cases, and these were neglected almost entirely. Most of the cultures collected during 1940 and 1941 were therefore obtained from cases belonging to larger outbreaks

of the disease. In March, 1942, when the number of available Vi-type phages had risen to three, it was decided to extend the investigation to include strains from sporadic cases or from small groups of cases. This change was a timely one, since the year 1942—proved to have the lowest number of notified cases of enteric fevers ever recorded in England and Wales. The total notifications, based on the weekly returns of the General Register Office, are shown for comparison in Table II.

The typing of a small fraction of the total number of cases such as has only been possible up to the present time, obviously provides a very rough indication of the frequency-distribution of the different Vi-phage types. Carefully organized surveys covering all parts of the country and carried out for a number of years, are required in order to obtain a reasonably adequate picture. It is, however, clear that the figures for 1940 and 1941 approximate more closely to the true frequency-distribution of the various types than the 1941 figures, which reflect the epidemic spread of Type 1 bacilli. The prevalence of this type during 1941 was obviously due to accidental causes, and not to any particular virulence of Type 1 bacilli.

It is of especial interest to note that the proportion of strains that could not be typed with the four type phages so far available has been very small. The highest figure was that for 1942—namely, 12% of the total number examined. In a similar series of cases of typhoid fever from this country (Felix, 1943) the proportion of untypable strains was slightly higher (69 out of 432 strains, or 15.9%). These figures are remarkable in view of the fact that the typhoid strains were tested against twenty-two different Vi-type phages, whereas only four phages were available for the typing of paratyphoid B bacilli. The significance of these observations is at present a matter for speculation. It is possible that by mere chance only a small number of the different Vi-phage types of paratyphoid B bacilli that are indigenous to this country were encountered during the present investigation. An alternative possibility is that the Vi antigen of *Bact. paratyphosum* B is not capable of variation to the same degree as the Vi antigen of *Bact. typhosum*—that is to say that the former has developed fewer Vi-phage types than the latter. Future investigations in this country and abroad will give the answer to these queries.

Paratyphoid B bacilli do not lose their specific Vi antigen as readily as do typhoid bacilli. In the corresponding series of strains of *Bact. typhosum* that had been typed by the bacteriophage technique (Felix, 1943) eight strains could not be typed because the cultures were Vi-negative "O" variants. In the present series of 714 strains of *Bact. paratyphosum* B

not a single strain remained untyped for that particular reason. All the cultures listed in Table II as untypable (Group Z) strains were examined in agglutination tests with pure O and pure Vi immune sera and were found to contain the heat-labile BVi antigen. On the other hand, paratyphoid B cultures that show the accepted criteria of "roughness" (Arkwright, 1930) cannot be typed. According to the degree of antigenic degradation which they have suffered, such cultures may or may not be lysed by anti-O phages; they are, however, invariably resistant to the action of anti-Vi phages.

Table III shows in chronological order those outbreaks of paratyphoid B fever in the British Isles that have been typed by the Vi-phage method. Many of these outbreaks have been described in detail in published reports, and the various epidemiological aspects raised by the authors have been reviewed in an interesting study by Savage (1942). No published accounts are available of those outbreaks mentioned in Table III to which no reference is printed in the table. The information concerning these outbreaks has been supplied by the pathologists from whom the cultures were received and by the General Register Office. The figures specified in Table II, when read in conjunction with the data recorded in Table III, will convey an indication of the distribution of the various types of paratyphoid B bacilli throughout the country. Table III shows that all the large outbreaks that occurred during 1941 were due to Type 1 bacilli.

This first survey of necessity furnishes only fragmentary information, but it shows clearly the scope of applicability of the new typing method. Its value as an epidemiological weapon is beyond doubt. The extent to which it can be usefully applied to the control of paratyphoid B fever depends solely upon the degree of co-operation between clinician, field investigator, and laboratory worker.

Summary

Anti-Vi bacteriophages that act specifically on *Bact. paratyphosum* B are described. Anti-O bacteriophages, on the other hand, attack strains belonging to many diverse *Salmonella* species.

Anti-Vi phages of *Bact. paratyphosum* B can be adapted to develop a high degree of specificity for particular strains, whereas anti-O phages are incapable of such adaptation.

Four separate and distinct Vi-phage types and subtypes of *Bact. paratyphosum* B have been identified so far, and a method of typing strains of paratyphoid B bacilli has been developed similar to that which was first devised by Craigie and Yen for the typing of typhoid bacilli.

Of 714 strains isolated from patients or carriers in Great Britain only 50 (7%) could not be typed by means of the available four Vi-type phages. The larger outbreaks of the disease in 1941 were found to have been caused by Type 1 strains.

The significance of paratyphoid-B Vi-phage types is the same as that of typhoid Vi-phage types. The typing of paratyphoid B strains isolated from sporadic cases or outbreaks is a valuable epidemiological weapon and is certain to be widely applied in the future.

We should like to express our thanks to the pathologists of the Emergency Public Health Laboratory Service and of many other public health or clinical laboratories for their co-operation throughout this investigation; to Dr. J. R. Hutchinson, Dr. W. H. Bradley, and Colonel C. Maddock of the Ministry of Health for help in collecting epidemiological data; and to Dr. C. M. Wenyon for hospitality at the Wellcome Research Institution.

A NOTE ON THE VALUE OF PHAGE TYPING IN THE INVESTIGATION OF AN OUTBREAK OF PARATYPHOID B FEVER

BY

J. R. HUTCHINSON, M.D., D.P.H.

Senior Medical Officer (Epidemiology), Ministry of Health

Felix (1943) recently related his experiences of the typing of typhoid bacilli by means of Vi bacteriophage (Craigie and Yen, 1938), and in a companion article Bradley (1943) gave an account of the first application of this new knowledge to field investigations in this country, and proved, in peculiarly difficult circumstances, its value to epidemiologists. As a natural corollary Felix and Callow proceeded to apply a like laboratory technique to *Bact. paratyphosum* B—the preliminary results of which are reported on page 127 of this issue—and an opportunity recently occurred of ascertaining whether the harmony between the laboratory and field findings demonstrated in typhoid also held in paratyphoid B fever.

In Ipswich in late July and early August, 1941, there were twelve primary cases of paratyphoid B fever notified from twelve different addresses in the town. Ten of the patients had not eaten any food away from home for many weeks. By the courtesy of Dr. Hunter, the medical officer of health, and Dr. P. H. Martin of the Emergency Public Health Laboratory Service, cultures of the causal organism recovered from the stools of all the patients were submitted to Felix for phage typing. He found that ten of the patients were excreting *Bact. paratyphosum* B Type 2 and two of the Type 1. Colonel Maddock, a Medical Officer of the Ministry made local inquiries and ascertained that, although no history of the consumption of one common article of food or drink from one source could be obtained, all the ten patients who had had no meals away from home had, at a material time, a common source of supply of "confectionery" from a shop in which an unattended case was found in the person of a daily domestic helper. There was no other common factor. This woman had continued at work for four weeks after she began to be ill, but ceased on Aug. 13, by which time she infected her daughter, who lived with her. The helper's daughter took her into the shop (she had no access to bulk supplies) and although they did not ordinarily include the handling of confectionery, there is ample evidence that she did this, and also assisted in conveying unwrapped confectionery from the bakery on the premises into the shop. The bakery supplied confectionery in bulk to certain other shops, to which none were traceable, and all the ten patients implicated were the same type was recovered from the stools of the secondary cases. Of the two primary cases excreting Type 1, neither had had any dealings with the shop in question. One was staying in another part of Suffolk and the other in a town in the Midlands.

From the beginning of 1941 to the time of the investigation fifteen cases of paratyphoid B fever had been notified from twelve different parishes scattered throughout seven parishes in the county (i.e., outside Ipswich), conjectured dates of infection of seven of the primary cases fell within the period during which the source of infection was the Ipswich shop. Two of the seven were present in the Ipswich shop. Both of the seven were to be excreting Type 2, the others Type 1. Both of the Type 1 cases lived in parishes contiguous to Ipswich and were customers of the implicated shop.

All the primary Type 2 cases in Ipswich and the neighbourhood, therefore, were associated with one shop in which an excretor of Type 2 was handling at a material time. There was thus complete harmony between the laboratory and the field findings.

THE TWO-STAGE AMPUTATION

PRIMARY PLANNED AMPUTATION IN THE PRESENCE OF SEPSIS

BY

E. A. JACK, M.B., F.R.C.S.Ed.

Major, R.A.M.C.

AND

J. CHARNLEY, M.B., F.R.C.S.

Major, R.A.M.C.

(No. 2 Orthopaedic Centre, M.E.F.)

Amputations in battle casualties at some interval after wounding present two main problems—namely, the level at which amputation should be performed, and the procedure to be adopted in dealing with the stump. Sepsis is the bogey. There is no doubt that if a formal flap amputation is performed a large proportion of the wounds become infected, with immediate danger to life and ultimate detriment to the stump. Authoritative publications unanimously recognize this fact, and explain it on the grounds that some hours after injury organisms invade the surface of the wound and migrate up the lymphatics of the limb. From the lymphatics they become liberated into the amputation stump. The M.R.C. War Memorandum No. 5 (1941) states that if 24 hours have elapsed since wounding infection of the amputation stump is almost inevitable; the American Medical Association *Handbook on Amputations* (1942) presents similar views, but puts the limits of the safe period at 12 hours; while other authorities vary between these times.

If infection of the stump is thus accepted as inevitable the only alternatives are either a low guillotine operation, with formal site-of-election amputation when all danger is passed, or a flap amputation at the site of election, the flaps being left widely open until sepsis subsides. Verrall (1941) suggests that it is sufficient to stitch the flaps loosely, with adequate drainage. During recent campaigns in the Middle East many cases have been received from the forward areas treated by these methods, and their subsequent behaviour has been observed. The flap amputation with loose suture or without suture was commonly performed during the Second Libyan Battle. During the Third Battle the low guillotine method was more in favour.

Of the former group few cases may be said to have pursued a satisfactory course. Almost all of the wounds became infected at some stage in the treatment, and the loose flaps became oedematous and retracted. A large discharging wound presented on which secondary suture was rarely possible, and the stumps healed only after a prolonged period of granulation. The eventual scar was often thin, puckered, and adherent to bone. If further plastic procedure on the stump is necessary and involves shortening of the bone, valuable length is lost.

The cases on which the low guillotine operation had been performed obtained perhaps, in the long run, the better end-results, because the final amputation was planned, but in the early stages their course was equally depressing. The misery of the large painful raw area, again frequently the site of prolonged infection, needs no elaboration. Reamputation is necessary, and on a patient who is just recovering from a severe ordeal the psychological effect of the news that a further portion of the limb must be lost is not the least of the disadvantages. Moreover, there is no guarantee that the final stump will remain aseptic unless the second amputation is delayed for a long time.

Experience of these methods yielded nothing but dissatisfaction at the prolonged morbidity which they entail.

Sources of Infection in the Amputation Stump

Infection may gain access to the amputation stump in three ways: (1) organisms may be present in the lymphatics and escape from them into the wound; (2) organisms may enter the wound from the skin edges or along drainage-tubes; (3) the wound may be contaminated at operation. The second source is perhaps a very common one in battle casualties,

in which multiple wounds, burns, or abrasions so often affect the skin close to the amputation field.

In the formal flap amputation, organisms once introduced into the wound find a ready site for multiplication owing to two main factors—the collection of blood or serum, and the release of normal tissue tension.

Unless operation is very much prolonged it is extremely unlikely that absolute haemostasis is achieved before stitching up. Small dead spaces remain between the flaps and about the bone-end which fill with blood-clot, and a tube drain or a loose closure affords nothing more than drainage by overflow. The flaps when cut retract, and are rarely drawn out to their normal tension again by the sutures, so that the circulation is altered in the flaps and there is a tendency to oedema, which renders the tissues more susceptible to infection. A bandage which brings enough pressure to bear at the end of the stump to eliminate pockets and to prevent oedema is almost impossible to apply, because the stump affords no purchase. Loose suturing of the flaps merely to allow drainage invites infection rather than prevents it.

The Two-stage Amputation

The two-stage amputation employs two principles. First, to combat implanted or invading organisms, sulphanilamide powder is introduced into the wound in large quantity to maintain a high local concentration. Secondly, to counter the predisposing conditions a large dry gauze pack is sutured under the flaps with its ends left projecting from the corners of the incision. The pack must be large and it must be of dry gauze. It must be large so that the flaps are sutured over it under moderate tension approximating to that obtaining in normal tissues; it must be of dry gauze so that it is absorbent.

During the first few hours after operation there is an out-pouring of serum from the raw surfaces, which soaks into the pack. By the capillary action of the gauze it is conducted out, via the extremities of the pack, into the dressing. At the same time a proportion of the sulphanilamide is dissolved by the serum and carried into the pack, which thus becomes a reservoir containing a solution of sulphanilamide in high concentration. Vaseline gauze will not fulfil these functions. The tension of the flaps over the pack maintains the circulation as nearly normal as possible, and at the same time produces through the medium of the pack an even pressure over the whole surface of the wound, thus preventing oedema and promoting effective haemostasis.

Technique of the Operation

The first stage starts as a standard flap amputation at the site of election. Often the vessels are seen to be surrounded by oedematous connective tissue, signifying lymphatic infection extending up the limb. When haemostasis has been rendered

FIG. 1.—Guillotine disarticulation through knee-joint prior to two-stage amputation.

as complete as possible, sulphanilamide powder is coated thickly over the wound. A dosage of 10 g. should not normally be exceeded for a mid-thigh amputation. The dry gauze pack is then introduced. Its size depends on the length of the flaps. Gauze roll folded on itself six or eight times to make a pack an inch and a half to two inches thick is recommended. It is carefully inserted well up into the folds of the flaps, so that it comes into direct contact with the whole surface of the

wound. Its ends project from the corners of the incision. (See Fig. 2.) The flaps are then pulled over it, and anchored with four or five sutures, and a well-padded dressing is applied. During the first 24 hours after operation there is usually some serous soakage through the dressings.

FIG. 2.—Appearance of stump before opening at second stage.

The second stage should be performed four or five days later. If it is done before the fourth day there is often some undissolved sulphanilamide still in the wound, and the full benefit has not been obtained. If left longer than five days there is a tendency for granulation tissue to grow into the pack, and bleeding follows its removal. The second stage must be carried out as a formal operation with the full aseptic precautions. The sutures are cut, the flaps very gently opened, and the pack peeled away from the surface of the wound. The flaps are soft and pliable, and are easily reflected. The wound is clean, dry, and a healthy pink colour. There are no

FIG. 3.—Stump before removal of sutures 14 days later.

haematomata. Sometimes about the bone-end there is a small area with a gelatinous appearance suggesting possible mild infection, but on culture this is found to be sterile. A second liberal coating of sulphanilamide powder is introduced, and the flaps are closely sutured without drainage. The sutures should be retained for 14 days.

If during the interval between stages the temperature does not quickly fall to normal, and there are signs of sepsis, the second stage should not be delayed. Should it be found, on removal of the pack, that infection has occurred and that there is suppuration in the wound, no harm has been done. The flaps are left open, and after control of infection a late secondary suture may be feasible.

The use of a dry pack is not claimed as original. It was tried out by one of us (J.C.) on two cases, at a time when site-of-election amputation with loose closure was being performed almost universally on battle casualties with bad results. The trial was satisfactory. Since then the procedure has been gradually evolved until the technique described above is now the routine for all amputations performed in this unit.

Report on Results

The two-stage method has been used in 26 cases, which are now reported.

1. Primary healing without any complication was obtained in 13 cases.

2. In 3 others, after final removal of the stitches, the skin margin slid apart for about half an inch, but quickly healed without sepsis when they were drawn together with strapping. In these cases the stitches were removed only 10 days after the second stage. Whipple (1940) reports that local sulphanilamide seems to delay normal primary wound healing, and as a result of this experience the stitches are now retained for 14 days after the second stage.

3. Three cases developed mild surface sepsis at the skin edges which did not interfere with the final healing or form of the stump. This group consists of cases in which the method was put to the most rigorous test, and in which closure by ordinary methods would almost certainly have been doomed to failure. Confidence born of success in preceding trials, and a desire to test the efficacy of the procedure to the full, are the excuses for having attempted a closer operation. One was a case of gas gangrene to the elbow, on which mid-arm amputation was performed one inch below an infected skin wound. The flaps looked quite clean at the second stage, and were closed. Mild sepsis broke down about an inch of the skin edges but the stump was healed after four weeks. The other two cases were both compound fractures of the femur with complications necessitating amputation. Preliminary wound toilet and sulphanilamide dressings had produced very mildly infected wounds. They came to amputation three and five days respectively after wounding. In each instance the first stage was performed through the wounds and fracture, damaged skin and muscle being excised before the introduction of the sulphanilamide and pack. At the second stage the wound appeared to be clean and dry except for minor infection at the corners of the incision, and the flaps were tightly closed except for these areas. The skin edges partly separated, but the wounds did not break down, and the stumps were healed, with linear scars, four to five weeks later.

4. Only 2 cases developed severe established infection with suppuration. In both of these pus was found on removal of the pack at the second stage, and the flaps were left open. In no case did sepsis develop to the extent of breaking down the wound after closure at the second stage of the amputation.

No case in this series came to operation within 24 hours of wounding. But with the introduction of air evacuation many arrived at the base inside two days, and in exactly half the cases reported amputation was performed within the first week when the danger from lymphatic infection should have been at its height. They are therefore comparable to amputations performed in the forward areas. Of the 13 cases, only one developed severe infection. The three instances of mild superficial infection belong to this group.

The remaining 13 were operated on at intervals varying from one to ten weeks after wounding, again with one failure. Seven were cases in which severe progressive infection had worn down the patient's resistance to breaking-point. Six were reamputations after low guillotine operation in the forward areas. The two-stage method made it possible to perform reamputation successfully very much earlier than would normally have been considered safe, even though the flap incision was often extremely close to the guillotine wound. The following case is an example:

Rfn. S. sustained a gunshot wound in the groin with division of the external iliac artery. Excision of groin wound and ligation of artery were performed and guillotine disarticulation of the knee, in a forward area. Ten days later the guillotine wound was still discharging freely. The groin wound was clean and granulating. (Two stage amputation with primary healing. Figs. 1, 2, 3.)

Conclusion

The procedures at present in vogue for amputation accept infection of the stump as inevitable. The guillotine seeks to side-track it, the loose-closure method to minimize its effects.

The two-stage operation aims at prevention of infection. In the cases reported it has yielded impressive results. Moreover, should it fail in its object no harm has been done.

The two stages of the procedure fit logically into the average time-lag between forward-area surgery and arrival at a base hospital. It is suggested that under modern conditions there should be no difficulty in giving the method a controlled trial.

PASTEURIZATION OF MILK AND INFANT MORTALITY RATES IN TORONTO, VANCOUVER, AND VICTORIA

BY

ALAN BROWN, M.D.

Professor of Paediatrics, University of Toronto

[In reply to an inquiry from Dr. Donald Paterson, Secretary of the British Paediatric Association, regarding statistics of infant mortality rates and pasteurization in Vancouver and Toronto, Dr. Alan Brown was able to collect through Dr. Bob Defries, Director of the School of Hygiene, University of Toronto, the following information, which he thinks presents the situation very plainly. It is, he says, quite unfair to compare statistics as statistics, because there are so very many factors to bear in mind. "We all know here that the climate is much more favourable on the Pacific coast than it is in the eastern part of the country. And, after all, the great importance of pasteurization lies in its reduction of all milk-borne infections. We have not had a case of milk-borne infection (including bovine tuberculosis) enter the Hospital for Sick Children—having lived in the city of Toronto and used nothing but pasteurized milk—since 1915." The inquiry arose out of a statement on infant mortality in Toronto made by Dr. A. H. Macdonald in a letter to the JOURNAL of Jan. 9, 1943.]

Discussion of pasteurization in the British Parliament was recorded in the *British Medical Journal* in September and December, 1942. In the issue of Dec. 19, 1942 (p. 727), there appeared a leading article entitled "Do Doctors Disagree about Pasteurization?" and several letters were subsequently published from correspondents. The following abstract from a letter from A. H. Macdonald, appearing in the correspondence columns of the *Journal* for Jan. 9, 1943 (p. 52), affords the probable basis of this inquiry from England regarding infant mortality rates and pasteurization in these Canadian cities: "The infant mortality in Toronto, where all milk is pasteurized, is double that in Victoria, Vancouver, where all milk is drunk raw. My own statistics dealing with large masses of children for 18 years show raw milk to be a good thing." (The letter refers to "Victoria, Vancouver." It is possible that the writer meant Victoria on Vancouver Island. As it is not clear, we have dealt with the cities of Victoria and Vancouver.)

Comment

1. The infant mortality rate for the city of Vancouver in 1940 was 25.6; for Victoria, 28.4; for Toronto, 38. The rate in Toronto is approximately one and a half times the Vancouver and Victoria rates.

2. The statement "in Victoria, Vancouver, where all milk is drunk raw," is incorrect, since in the report from the Medical Officer of Health for Vancouver, made to the Committee on Milk of the Canadian Public Health Association, as relating to 1938, the proportion of milk pasteurized in that city was given as 79%; and in a similar report from the Medical Officer of Health for Victoria 50% was stated to be pasteurized.

Discussion

In considering the causes, as recorded statistically, of infant mortality under the headings of (a) "Diseases Peculiar to Early Infancy"; (b) "Communicable Diseases"; (c) "Acute Respiratory Infections"; (d) "Diarrhoea and Enteritis"; and (e) "All Other Causes," for Toronto and Vancouver, reference will be made to the data for the years 1919, 1929, and 1939. These three 10-year periods indicate the significant changes.

(a) *Diseases Peculiar to Early Infancy*.—In 1919 Toronto had a rate of 41.2 for this group of causes, in contrast to Vancouver, which had a rate of 26.3. Ten years later (1929) the Toronto rate had fallen to 37 and the Vancouver rate to 16.3. In 1939 the Toronto rate had fallen to 25.7 and the Vancouver rate to 13.1. The Toronto rate is practically double the Vancouver rate. As this group of causes represents more than half of the total infant mortality it is evident that much of the difference between the rates for Toronto and Vancouver is due to this group of causes, which includes prematurity, etc.

(b) *Communicable Diseases*.—The rate in 1919 for this group of causes was 7.4 in Toronto and 5.2 in Vancouver. Ten years later (1929) the Toronto rate fell to 5.7 and the Vancouver rate to 1.6. In 1939 the Toronto rate was 1.5 and the Vancouver rate 0.5. It will be noted that the rate in Toronto is three times the rate in Vancouver; but the total number of deaths from communicable diseases is quite small and does not explain the difference between the gross infant mortality rates.

(c) *Acute Respiratory Infections*.—In Toronto the rate in 1919 for this group of causes was 16.3, and in Vancouver 7.4. In 1929 the Toronto rate was 6.5 and the Vancouver rate 5.7. In 1939 the Toronto rate was 4.8 and the Vancouver rate 2.1. It will be noted that the Toronto rates are again almost double the Vancouver rates; but the total number of deaths contributed by this group of causes is small and does not represent a major factor in the difference between the two rates.

(d) *Diarrhoea and Enteritis*.—In 1919 the Toronto rate was 11.5 and the Vancouver rate 5.2. Ten years later (1929) the rate for Toronto had fallen to 9.7 and for Vancouver to 1.4. In 1939 the rate in Toronto was 2.2 and in Vancouver 0.

(e) *All Other Causes*.—In 1919 the rate in Toronto was 25 and in Vancouver 12.6. In 1929 the rate in Toronto was 19.3 and in Vancouver 8.5. In 1939 the rate in Toronto was 9, and the rate in Vancouver also was 9.

From this analysis it is evident that the major differences in the rates in Toronto and Vancouver are accounted for largely by the differences in the rate in the group of causes entitled "Diseases Peculiar to Early Infancy." It is interesting to note that the fall in death rate in the group of diseases to which pasteurization would primarily be related—namely, diarrhoea and enteritis—is now approximately the same in both cities and represents a very small number of deaths.

Reference is not made to the city of Victoria because data of infant mortality rates by groups of causes were not available and, further, because the figures are for Greater Victoria, which includes adjacent municipalities. As, however, the infant mortality rate for Victoria is only slightly higher than that of Vancouver, analysis would probably yield similar data.

Graph showing infant mortality rates in Toronto, Victoria, and Vancouver from 1914 to 1940.

In considering this question of the difference in infant mortality rates of certain cities on the Pacific coast it is of interest to refer to a paper by Bellows and Reed published in 1934 in the *American Journal of Hygiene* (vol. 20, p. 565) entitled, "The Effect of Certain Environmental Factors on Urban Infant Mortality Rates." In this article a table is presented giving the crude infant mortality rates for cities in the United States having a population of over 100,000 and under 1,000,000, corrected for five factors—temperature, latitude, relative number of foreign-born, relative number of coloured, and unemployment in manufacturing and mining. Of the seven cities with the lowest crude infant mortality rate, six were on the Pacific coast. Seattle leading with the rate of 56.6. To each of these a substantial correction was considered necessary, ranging from plus 9 to plus 28. Seattle and Portland, Ore., retained the lead among the first seven; in fact, among the first ten. Others on the coast did not fare so well. "The first ten cities whose crude rates were all below 80 have marked increases in their corrected rates. The group will be seen to include all of the cities located on the northern Pacific coast, where climate is relatively favourable. Allowance for this factor, and for the lack of industrialization in the Pacific cities, was largely responsible for the changes in their rates. Adjustment for the small industrial development was the principal

correction in the other cities in this low mortality group (the first ten), temperature in this case being a factor of minor importance."

This subject was further considered by Dr. L. A. Pequegnat, Deputy Medical Officer of Health, Toronto, who presented a paper entitled "The Present Problem in Infant Mortality" to the Academy of Medicine, Toronto. The paper was published in the *Canadian Public Health Journal* (1938, 29, 477). It reproduces a table of Bellows and Reed's. In this paper the rates for Toronto and Vancouver are presented for the years 1930 to 1935. In 1930 and 1935 the infant mortality rate in Toronto was double the Vancouver rate. It would seem, therefore, that the lower rates of Vancouver and Victoria require in their consideration some of the factors studied by Bellows and Reed. That climate alone is not the factor is evidenced by the fact that the rate in Calgary in 1940 was 31.2 and in Edmonton 30.6, in comparison with 25.6 in Vancouver and 28.4 in Victoria. Figures for other cities in Canada are: St. John, N.B. (65% of milk pasteurized), infant mortality rate 55 (1940); Montreal (95% pasteurized), rate 70 (1939) and 58 (1940); Three Rivers, Que. (60% pasteurized), rate 97 (1940). In Ontario all municipal milk supplies were required to be pasteurized in 1938. Data for 1940 give the following infant mortality rates: Hamilton 33, London 36, Kitchener 37, Ottawa 49.

From these rates it is evident that neither climate nor pasteurization of milk gives an answer to the differences in rates. The larger number of deaths due to prematurity, etc., is an important factor.

THE OCULAR CRITERIA OF DEFICIENCY OF RIBOFLAVIN

BY

M. K. GREGORY, M.B., Ch.B., D.O. Oxon

Since Bessey and Wolbach (1939) showed that corneal vascularization was a sign of riboflavin deficiency in rats, and since the publication of two papers on ocular manifestations of ariboflavinosis, by Kruse *et al.* (1940) and Sydenstricker *et al.* (1940), there has been a spate of enthusiastic but uncritical investigations. It is therefore necessary that there should be some attempt to clarify the confusion of thought and to correct the looseness of terminology that has arisen. Evidence of this confusion is to be found, for example, in a recent report of an investigation by Scarborough (1942) in which he has taken the sign of circumcorneal injection as being of primary importance. This sign can occur in early ariboflavinosis, but it certainly is not pathognomonic; and I do not find anything in the paper by Sydenstricker *et al.* (1940), which is quoted by Scarborough, to indicate that this isolated sign should be so interpreted. A further discrepancy which I have noted occurs in the two papers mentioned above, which in one place describe the earliest change noted as being a superficial invasion of the cornea by capillaries, and in another place say that "the earliest and most common sign of ariboflavinosis is circumcorneal injection." Also the terms "circumcorneal injection" and "ciliary congestion" are used indiscriminately without indicating whether just some degree of fullness of the superficial pericorneal vessels is meant or whether there is an intense ciliary blush. From my own recent observations and from verbal corroboration by other observers I question whether what is clinically known to ophthalmologists as circumcorneal injection is necessarily an accompaniment of mild early corneal vascularization as we see it in this country.

As the ocular changes in early deficiency of riboflavin are concerned with the vascular supply of the limbus it is essential that observers first should have an exact knowledge of the normal blood supply and arrangement of vessels at the limbus;

secondly, they should have an accurate idea of the changes which, in the light of our present knowledge, may be expected to occur; and, thirdly, they should know what other conditions may produce somewhat similar appearances and how these may be distinguished. I propose to give a brief outline of these three points.

Fortunately it is rare at present for nutritional deficiencies to be more than slight in this country, and therefore, as it is the mild rather than the gross changes that are being considered, the picture that we may expect to find will scarcely be comparable with the fully developed cases described by Sydenstricker *et al.* (1940) and Kruse *et al.* (1940). I am not considering such signs as pigment deposits on the iris and mydriasis, as the significance of these has not yet been adequately established.

The Normal Blood Supply of the Limbus

The blood supply of the pericorneal region comes from the anterior ciliary arteries arising indirectly from the ophthalmic arteries via the arteries of the four recti muscles, each tendon being accompanied by two, except the external rectus, which has only one. These arteries pass forward on the episclera, giving branches to the sclera, corneal margin, and conjunctiva. The main branch of each artery pierces the sclera about 4 mm. from the corneal margin to enter the ciliary muscles, where it anastomoses with the long posterior ciliaries to form the circulus iridis major. Before piercing the sclera the anterior ciliary arteries give off the anterior conjunctival branches, which run forward deep to the posterior conjunctival arteries and anastomose to form the pericorneal plexus, consisting of a series of arcades parallel with the corneal margin. These give off final branches, marginal loops which bend round on their tracks to form venules leading into a venous plexus built up on similar lines. The anterior conjunctival arteries also give off small posterior branches to anastomose with the posterior conjunctival arteries, which come from the palpebral branches of the nasal and lacrimal arteries of the lids.

The pericorneal plexus is in two layers—the superficial conjunctival and the deep episcleral. This distinction is important because in superficial affections of the cornea the superficial portion is injected and may rightly be termed circumcorneal injection, whereas in diseases of the iris, ciliary body, or deep part of the cornea the deep episcleral portion becomes congested and gives rise to the rose-pink or violet band typical of ciliary congestion. This deep ciliary congestion is always a serious sign as indicative of uveal disease, but superficial circumcorneal injection can be transiently produced by vigorously rubbing the eye for a moment; and it results from irritations such as exposure to wind, cold, bright light, mild chemical irritants, mild infection, and numerous other causes. From such causes there must be a considerable proportion of the population showing circumcorneal injection, which would fit the description given in the paper by Sydenstricker *et al.* (1940) as "often it was grossly visible, frequently it could be seen with a hand lens or ophthalmoscope, and always it was obvious on slit-lamp inspection as marked congestion and proliferation of the limbic plexus." On this point I would ask what evidence there is that there is any real proliferation and not only engorgement of pre-existing but empty and therefore invisible vessels.

The extent to which the vessels may, within normal limits, extend on to the cornea should also be defined. The limbus is the whole zone in which the sclera and cornea overlie owing to the edge of the cornea being inset like a watch in a groove in the sclera. Though it is said to be 1 mm. width, it is very variable, often being much wider than that. With the slit-lamp the whole width of the limbus appears as ground glass, increasing in opacity peripherally. It may be segmented by digitations or may appear homogeneous. The marginal plexus is described as occupying a triangular area whose apex lies where Bowman's membrane ends and whose base is formed by episcleral and scleral tissue (Wolff, 1938). Thus it is normal for vessels to occupy the whole width of the limbus, and there is not necessarily an avascular zone between the plexus and sclero-corneal junction; and capillaries which do not extend beyond the limbus thus defined are considered to be within the limits of normal.

Ocular Appearances in Riboflavin Deficiency

The chief sign is a superficial invasion of the cornea by very fine capillaries arising from the apices of the marginal loops. These lie just deep to the epithelium and extend evenly as streamer-like vessels which anastomose to form a series of loops from the apices of which more capillaries grow towards the centre, giving the appearance, with the slit-lamp, of fine almost parallel vessels extending on to the cornea round the whole of its periphery in both eyes. The extent of invasion may differ in each eye. Superficial and interstitial opacities develop at various stages, but are definitely later in occurrence than the initial vascularization. In more advanced cases the vessels penetrate to a greater depth into the substantia propria. In a proportion of cases there is some injection of the pericorneal plexus, which in mild deficiency is confined to the superficial conjunctival layer.

Other Causes of Corneal Vascularization

The cause of the most extensive vascularization of the cornea is interstitial keratitis, in which the new vessels invading the cornea come from the anterior ciliary arteries as they pass deeply through the sclera, and thus, as the sclera is opaque, they disappear behind the limbus. With the slit-lamp they are seen to lie in the posterior half of the substantia propria over the whole area of the cornea and are irregular in arrangement. In contradistinction to the superficial centripetal regular arrangement of capillaries in riboflavin deficiency.

Some other conditions in which vascularization of the cornea may occur are vitamin A deficiency, tryptophan deficiency, injury of corneal epithelium due to chemical irritants, diseases causing pannus, such as trachoma, phlyctenular keratitis, pannus degenerativus, and also any superficial keratitis.

Bessey and Wolbach (1939) describe corneal vascularization, similar to that due to lack of riboflavin, in rats deficient in vitamin A; but this is not usually described as a sign associated with keratomalacia in human subjects, nor have I found it as an early sign in people known to be deficient in vitamin A. Albanese and Buschke (1942) describe vascularization of the cornea similar to ariboflavinosis in cases of tryptophan deficiency in both adult and growing rats and reversible by giving tryptophan. It is unlikely, however, that this specific deficiency will arise without other evidence of deficiency of protein. Vascularization from chemical causes is not usually bilateral nor so regular and uniform, except in the case of exposure to chemical vapour, which can give a comparable picture; but the history and the somewhat atypical appearance should enable it to be differentiated.

The vascularization of trachomatous pannus is confined to the upper part of the cornea under the upper lid and, as is characteristic of all pannus formation, there is infiltration of granulation tissue and leucocytes between and around the vessels. Phlyctenular pannus may occur right round the periphery, but it is of the pannus type of vascularization with coarser vessels, and can be further distinguished by symptoms of laceration, photophobia, irritation, and blepharospasm, which are extreme in this condition. Pannus degenerativus occurs in old blind eyes and starts in the substantia propria.

Out of 1,059 presumably normal people whom I recently examined in search of signs of riboflavin deficiency 31 (3%) showed corneal vascularization compatible with ariboflavinosis, and of these only 14 were recorded as having any injection or even fullness of the limbic plexus. Among these 31 only 5 complained of any subjective symptoms such as burning, irritation, or laceration, and none volunteered a history of twilight blindness, which Pock-Steen (1939) asserts is an early sign. In only 4 cases was the visual acuity in both eyes less than 6/6. Eight cases showed other signs of riboflavin deficiency such as glossitis or cheilosis. In all these subjects a full clinical examination was carried out and their night vision was tested. These results will be published at a later date.

I would suggest that, as in the cases examined by Scarborough (1942) the greatest incidence of pericorneal injection occurred in the age group 50-59, this may be a normal finding, since people of this age rarely have the clear white limbus normally found in youth.

Since the 47 patients in Sydenstricker's investigation were being given 300 mg. of nicotinic acid daily it appeared possible that the vasodilator action of this drug might have some influence on the high incidence of circumcorneal injection found. In order to test the possibility of this, I examined the eyes of 6 normal medical students and then administered 200 mg. of nicotinic acid by mouth. When examined 20 to 30 minutes later two showed marked injection of perilimbal plexus, three a moderate degree of injection, and one very little change. These subjects continued to take 200 mg. daily for five days, and were finally examined again 8 hours after taking the last dose. Three showed no increased vasodilatation compared with their original state and three showed a very slight but not significant increase. A further series of 6 subjects were given 200 mg. of nicotinic acid after examination, and then examined at half-hourly intervals. One showed marked, three moderate, and two only slight injection. The two slight and one moderate had returned to normal in 1½ hours, and two moderate and one marked case had returned to normal in 2 hours. Thus it is inferred that the local effect of these doses of nicotinic acid is important only within 2 hours of its administration.

It may be said that I have committed the error that I have criticized in Scarborough's paper in laying the emphasis on one isolated symptom—viz., corneal vascularization. This at least is more justifiable in that it is generally recognized as a more characteristic sign, and, according to Bessey and Wolbach (1939), "it precedes all other demonstrable lesions of the deficiency." Even so, I should refrain from diagnosing a definite deficiency on this single finding in the absence of other signs, such as cheilosis or the typical glossitis, unless it responded to treatment with riboflavin.

I would, however, advocate most strongly that those interested should acquire an accurate picture of the signs indicative of this deficiency, so that large quantities of this expensive vitamin preparation, which will presumably be so valuable in post-war Europe, will not be given empirically or unnecessarily, and considerable time will not be wasted in investigating signs that have no real diagnostic value.

Summary

An attempt has been made to elucidate early ocular signs due to riboflavin deficiency. Previously, circumcorneal injection has been given an unduly prominent place by other workers, whereas corneal vascularization is a more reliable sign. This is of a distinctive type, consisting of fine streamer-like centripetal arranged vessels invading all round the cornea in both eyes.

The normal anatomy of the part of the eye involved has been described, and other pathological conditions which might give comparable appearances have been briefly discussed.

An investigation of the effect of administration of nicotinic acid as a possible cause of circumcorneal injection has been described.

In spite of outbreaks of small-pox in surrounding territories, since Feb., 1941, not a single case has been reported within the borders of Southern Rhodesia, yet between 1937 and Feb., 1941, the colony had over 2,600 detected cases of small-pox, almost entirely among natives, though the disease was generally of a mild type. It is worthy of note that a vigorous vaccination campaign has been carried out by the Public Health and Native Departments, as a result of which 400,000 natives (nearly a quarter of the colony's native population) were vaccinated. The Public Health Department now has a trained unit consisting of health inspectors and native vaccinators who systematically ensure effective vaccination. Last year the unit vaccinated 147,000 people. When, in Oct., 1941, small-pox broke out in Francistown, Bechuanaland, a few miles across the Rhodesian border, the unit carried out a vaccination campaign along the border for hundreds of miles and not a single case of small-pox developed on the Rhodesian side.

RUPTURE OF RECTUS ABDOMINIS MUSCLE DURING PREGNANCY

BY

RUFUS C. THOMAS, F.R.C.S.Ed., M.R.C.O.G.

Obstetric Consultant, County Borough of Croydon

Rupture of the rectus abdominis muscle is a very rare complication of pregnancy. Mr. T. J. Shields, librarian of the British Medical Association, to whom I am indebted for looking through the literature, was able to find nine instances, of which seven were recorded in foreign journals, and two—Hobbs (1938) and Ashkar (1939)—were published in this country.

Two Cases in the Literature

The patient described by Hobbs was a 6-para, almost at term, who had had a cough for a month, associated with occasional pain in the left upper abdomen. Following a bout of coughing she had a sudden severe pain in the left side of the abdomen, and was admitted to hospital about twelve hours later in a condition of collapse. She died in less than an hour, before a blood transfusion could be given. Necropsy revealed three pints of blood and clot in the sheath of the left rectus, with one large recent tear in the posterior surface of the muscle at the junction of the lower and middle thirds, and evidence of older tears and haemorrhages in the upper segments. Hobbs concluded that the vessel involved was the deep epigastric artery. The uterus contained a 9½-lb. foetus and some excess of liquor amnii.

Ashkar's patient was an 8-para, five months pregnant. She, too, had had respiratory trouble in the form of acute bronchitis a fortnight previously, but the acute abdominal pain associated with the muscular lesion occurred while she was sweeping the floor. A large blood-clot was removed from the right rectus sheath. A transverse, ragged, and incomplete tear was found in the muscle at the level of the umbilicus. This was sutured, and the patient made an uneventful recovery, the pregnancy proceeding to normal delivery at term.

It will be seen that, except for the difference in the duration of the two pregnancies, there is a close similarity in the train of events in the above patients. Both had coughs for some time before the final rupture of the muscle, though in the second case there was the added exertion of sweeping the floor. The muscle gave way in each patient at the umbilical level, which corresponds with the tendinous intersection between the lower and middle thirds. This is about the level of the lower edge of the posterior portion of the rectus sheath, the semilunar fold of Douglas, over which the deep epigastric artery passes before entering the deep surface of the muscle. The pathology of the muscular rupture seems very similar to that met with in rupture of the quadriceps extensor muscle after slipping off a curb or step.

The Present Case

The case I now record was a 3-para who had attended the Croydon County Borough ante-natal clinic from the ninth week of the present pregnancy. Her previous children had been 9 lb. and 10½ lb., delivery in each instance being spontaneous. She had remained well in the third pregnancy until the 36th week, when she had a cold. Two days later, on March 19, 1937, she went to see her own doctor because of a pain in the right side of the abdomen. He examined her the next day, when the pain had become acute. She was admitted to Mayday Hospital at 10.50 a.m. on March 20.

On examination she was complaining of acute abdominal pain, chiefly on the right side, but the whole of the abdomen was rigid. The pulse rate was 92, and the temperature 97°. She looked pale and somewhat shocked. Palpation of the abdomen showed generalized tenderness, but foetal parts could not be felt, nor could the fetal heart be heard. There was no vaginal bleeding. A catheter specimen of urine showed no albumin. The blood pressure on March 17 was 116/80 mm. Hg. A diagnosis of concealed accidental haemorrhage was made, and in view of her condition the membranes were ruptured under general anaesthesia. About a pint of liquor amnii was let out, and was found to be not blood-stained. The os was admitted one finger, and the vertex was presenting. It was not possible to say whether labour had actually started, but a Muesellum forceps was attached to the foetal scalp and a 1 lb. weight applied to stimulate labour. During the next twelve hours her condition became slowly but steadily worse, the pulse rate rising to 100. The abdominal pain was increasing, but there were no signs of labour having begun. In view of the deterioration in the general condition it was decided to empty the uterus by Caesarean section. Under general anaesthesia a right-sided pararectal subumbilical incision was made. On opening the sheath of the right rectus muscle it was found to be full of fresh blood-clot, which extended from the symphyseal region right up to the ensiform cartilage, and the umbilical region had spread over to the area between the

peritoneum and the left rectus muscle. The right rectus muscle appeared to be almost completely disorganized. No definite bleed point could be seen. Nearly two pints of blood-clot was removed from the immediate area around the incision. I was now in some what of a dilemma as to the further procedure. It was certain that labour would start very soon, and if delivery per vaginam was allowed there was considerable risk of the sutured abdominal giving way. The uterus was therefore evacuated by a lower-segment Caesarean section. The foetus was dead but not macerated, I think there can be no doubt that its death was the result of maternal shock. The uterus and abdominal incisions were closed the usual way, but a corrugated drain was placed within the sheath of the right rectus muscle from the umbilical region to the suprapubic end of the incision. Recovery was without further incident but the clot which had been left in the upper portion of the rectus sheath could be felt as a hard mass for some months after.

The patient had sustained a third-degree perineal laceration during the birth of her first child that had never healed, and she had practically no anal control for eight years; there was a marked cystocele as well. In March, 1938, she was readmitted, and I carried out an anterior colporrhaphy and posterior colpoperineorrhaphy with reconstruction of the anal canal, followed a month later by sterilization by excision of both Fallopian tubes. The incision for the latter operation was a left pararectal subumbilical one, and I was therefore not able to see the condition of the right rectus muscle. By palpation it appeared to be very deficient, but no trace of the mass of blood clot in its upper part could be felt. Some adhesions between the peritoneum and the omentum had to be separated, but the abdominal cavity was otherwise normal. She again made an uneventful recovery, and regained almost perfect anal control. Her joy at a gratitude over this result, after nine years of incontinence, was pathetic. Her only complaint after getting up was a feeling of abdominal discomfort, which was relieved by the fitting of an abdominal belt.

Summary and Discussion

A case of rupture of the rectus abdominis muscle during pregnancy is reported. The records of two previous instances of the same condition are referred to, and it will be seen that there is great similarity in the train of symptoms in the three cases. All had had respiratory trouble just before the accident condition occurred; all were multiparae, in whom it is probable that the rectus muscle had been weakened by previous pregnancies, the muscle finally giving way at the weakest point—the tendinous junction between the lower and middle thirds—the rupture being precipitated by sudden abdominal strain. The artery involved was almost certainly the deep epigastric, which passes into the deep surface of the rectus muscle just above the umbilical level.

The condition is rare, and can give rise to difficulties of diagnosis. Hobbs does not state what he thought the probable diagnosis was, but only that the condition of his patient suggested a severe haemorrhage, and she died in less than an hour after admission. In Ashkar's case the preliminary diagnosis was of an ovarian cyst with a twisted pedicle, the diagnosis being based on the sudden acute abdominal pain, the presence of a mass high up in the abdomen, tenderness and muscular rigidity, fever, and leucocytosis. In my case the signs closely simulated those of concealed accidental haemorrhage. Though my decision to empty the uterus was based on a wrong diagnosis, the fact that I acted upon it probably averted a fatal issue.

I have seen one other case of traumatic rupture of the right rectus muscle, which I reported in the *Lancet* in 1933. It occurred in an Indian port labourer, as a result of being pinned between the buffer of a railway truck and a bag of sugar which had been swung by crane from a barge. In this case, also, the rupture occurred at the level of the umbilicus, but the whole abdominal wall was burst open, resulting in the extroversion of several feet of small intestine and the crushing of several coils of adjacent gut. There was in this case singularly little shock and no haemorrhage worth mentioning. He made an uninterrupted recovery after resection of six feet of small gut and resuture of the disrupted abdominal wall which was closed without drainage.

The case record is published by courtesy of Dr. Oscar M. Holden, Medical Officer of Health, County Borough of Croydon, to whom my acknowledgments are due.

Medical Memoranda

Treatment of Prostatic Carcinoma by Oestradiol and Diethylstilboestrol

The fact that American work on this subject is not widely known in this country leads me to report the following cases.

CASE I

A doctor aged 72 was seen in the spring of 1941. Carcinoma of the prostate was the clinical diagnosis, and this was confirmed by biopsy when Mr. Millin of London performed a perurethral removal of the prostatic "flap" to relieve increasing urinary obstruction. After an initial improvement the patient went gradually downhill with increasing urinary obstruction. X-ray examination showed metastases in the lumbar spine, and symptoms suggested metastases elsewhere. From July, 1942, because of general weakness and acute back pain he was only able to get out of bed for short periods, and from Oct., 1942, he was completely confined to bed. By the end of December he was requiring three or four hypodermic injections of morphine gr. 1/3 in 24 hours, micturition was very painful with cramp-like pains, the left thigh was swollen with lymphatic oedema, appetite was non-existent, and his colour was grey. There was no evidence of infection of the urinary tract; the prostate felt per rectum was hard, nodular, and large.

Early in Jan., 1943, treatment by intramuscular injection of oestradiol benzoate was started, tentatively at first, and then, after reading the paper by Kahle, Ogden, and Getzoff (1942), more boldly, 42 mg. (420,000 units) being given in the first 28 days. Improvement in the general condition, appetite, and colour was rapid and dramatic. This was followed more slowly by relief of the urinary symptoms. The back pain disappeared, the morphine was reduced, and the change in three weeks from a grey sufferer to a pink-cheeked man with a good appetite had to be seen to be believed. On examination per rectum the prostate was softer and had decreased in size.

Improvement since that date has continued, and he is now able to walk upstairs and out of doors for short distances. In 80 days he has had 159 mg. of oestradiol benzoate, 5 mg. being given on alternate days. In view of his good condition the dose has now been cut down to 5 mg. twice weekly. The only adverse effects noted were painful nipples and some allergic nasal catarrh; in view of the markedly beneficial results these symptoms were borne with some degree of equanimity.

It must be remembered that this patient is a doctor who, with full knowledge of his disease, at first regarded the treatment with a natural medical scepticism, polite but nevertheless apparent.

CASE II

A retired artist aged 60 was seen in Nov., 1942, with an enormous and very hard prostate. Urinary obstruction was increasing, and was obviously soon due to be complete. As his condition was very poor it was agreed to await developments, and to perform a permanent suprapubic drainage when absolutely necessary.

On Jan. 3, 1943, treatment was started with oestradiol benzoate, 1-mg. doses being given daily. This was followed by complete urinary obstruction, and tied-in catheter drainage was adopted. The injections were stopped. In spite of a clean urine the patient went downhill, and in view of Case I the injections were restarted with larger doses, 5 mg. being given on alternate days. Improvement in general condition, appetite, and colour was rapid and sustained, and in a month he had put on about 1 st. in weight. As catheter drainage was still necessary a permanent suprapubic catheter was inserted under local anaesthesia.

In 71 days he received 155 mg. of oestradiol benzoate. On March 15, 1943, he was changed over on to diethylstilboestrol (Boots), 5 mg. being given on alternate days, and improvement has been maintained. He is now able to walk some distance.

CASE III

This patient, aged 71, was seen on Jan. 15, 1943, with advanced carcinoma of the prostate, marked enlargement of the deep inguinal lymph glands, and lymphatic oedema of the thigh. His symptoms dated back for twelve months, and his weight was under 8 st. His appetite was non-existent.

This case was seen by Mr. Bernard Ward of Birmingham, who immediately performed a partial perurethral resection in order to avoid permanent suprapubic drainage.

On the patient's return home his urinary symptoms had been relieved, but his general condition was still poor and his appetite still absent. On Feb. 19 he was started on diethylstilboestrol (Boots), 5 mg. being injected daily, and 215 mg. being given in 44 days. Improvement was rapid and obvious after 7 days, and is being maintained. Over 1/2 st. in weight has been gained in six weeks. Again appetite, colour, and general condition were the first to respond, but improvement in urinary symptoms and the oedema in the thigh is following. Painful nipples are present in this case.

SUMMARY AND CONCLUSIONS

Three cases of carcinoma of the prostate, all advanced, are reported.

Improvement by treatment with large doses of oestradiol benzoate and diethylstilboestrol was marked and sustained. (My feeling is that the former works better than diethylstilboestrol, but it is much more costly.)

Improvement of secondaries appears to take place with that of the primary growth—Schenken, Burns, and Kahle (1942).

From a limited experience it seems that some form of drainage should precede the starting of this treatment, preferably perurethral diathermy.

The giving of large doses of diethylstilboestrol is theoretically carcinogenic; in advanced cases of carcinoma of the prostate this risk may, I think, be taken.

G. HARVEY DUNCAN, F.R.C.S.

Pseudocyesis Simulated in a Male

The following case of hysteroneurosis may be considered worthy of record on account of the rarity of the condition. A feature of interest was the close association between the patient's clinical symptoms and the initial and final stages of his wife's pregnancy. The case responded to psychotherapeutic treatment.

CASE RECORD

In June, 1942, a soldier aged 27 was admitted to the medical wards of an emergency hospital as a case of "2 abdominal tuberculosis." He remained in hospital for 40 days, during which time the abdominal distension which was the only abnormal finding in his case progressively diminished. He was thereafter discharged to his unit, and from this period onwards he remained well and constantly employed at his Service duties. On Feb. 20, 1943, he was again admitted to the medical unit of an emergency hospital with a complaint of abdominal distension and epigastric pain of one week's duration. The history revealed the sudden onset of abdominal pain while on parade, followed by abdominal distension and vertigo. Vomiting quickly ensued, which was associated with the putting on of his tunic belt, and did not occur at other times. The severity of his condition progressively increased until his admission to hospital.

Physical Examination.—He was a well-developed man, displaying considerable abdominal distension. There was an absence of tenderness to palpation, and the distension was uniform throughout, offering resistance to deep palpation. This resistance was most marked over an oval area extending from the umbilicus to the symphysis pubis in the middle line and measuring about 5 in. in breadth at its widest point. The circumference of the abdomen was 41 in. at the mid-umbilical level. There was an absence of any localized rigidity or dough-like feeling of the abdomen. With the exception of the physical signs of anxiety, which were pronounced, nothing of clinical interest was elicited on physical examination. Radiography revealed negative findings; test-meal curves were within normal limits; tests for occult blood were negative; and examination of the various systems failed to disclose any abnormalities. On March 3 the abdominal distension was still present to the same degree as on his admission to hospital.

Psychological Examination.—There was well-marked anxiety present. He was morbidly introspective, reticent, and monosyllabic. It appeared that his wife was shortly to be confined and that he had made attempts to secure compassionate leave on account of this. It was significant that when he first learned of his wife's pregnancy in June, 1942, symptoms similar to those on account of which he had been admitted to hospital ensued. On Feb. 13 he had received a letter from home at 8 a.m., and his abdominal distension resulted at 11 a.m. on the same day. Temperamentally he was of a nervous, highly strung, and emotional type, and had previously displayed a deep interest in religious affairs.

In view of the symptoms presented, the diagnosis of hysteroneurosis was made and it was decided to initiate treatment by "reinforced" suggestion. On March 3 12 c.cm. of a 1.5% solution of pentothal sodium was administered intravenously and an explanation of the causative mechanism underlying his condition was given to him. While in the narco-analytical state suggestion was carried out. The abdominal distension slowly subsided and at the mid-umbilical level was reduced to 30 in. The reduction was maintained at this level for a period of one hour subsequent to treatment, and thereafter slowly returned to the former level. On the following day suggestion was given with the patient in the waking state, when the distension again subsided. On March 15 the distension had entirely disappeared; there was complete freedom from pain on deep pressure, and he was able to be employed on light ward duties. On April 15 he was discharged to his unit with a recommendation for a lowering of his category. Leave was granted in order to enable him to visit his wife, and he had volunteered the statement that he now felt better in health than he had done for the past ten months.

I wish to express my indebtedness to Dr. J. Norman Cruickshank for his original recognition of the underlying causative factors, for his co-operation in granting facilities for the examination and treatment of this case, and for his permission to publish the results.

Physician, Emergency Medical Service.

Reviews

SEA DISEASES

Sea Diseases. The Story of a Great Natural Experiment in Preventive Medicine in the Royal Navy. By R. S. Allison, M.D., F.R.C.P. (Pp. 218. 25s.) London: John Bale Medical Publications.

R. L. S. wrote: "But the sea is our approach and bulwark; it has been the scene of our greatest triumphs and dangers; and we are accustomed in lyrical moments to claim it as our own. The prostrating experiences of foreigners between Calais and Dover have always an agreeable side to English prepossessions. A man from Bedfordshire, who does not know one end of the ship from the other until she begins to move, swaggers among such persons with a sense of hereditary nautical experience." Yet the self-examination of most of us would probably reveal that *Roderick Random*, the novels of Marryat, and a few witticisms of Dr. Samuel Johnson contain all we know of life in the Navy of our ancestors.

Forty-eight years ago the reviewer was presented by his form master with Commander Charles Robinson's *The British Fleet*. It was a good prize for a boy because it contained many attractive pictures, but, consulted in later years, when the reader's interest in medicine had developed, the book was less satisfactory; its 560 pages include two brief references to sickness, a few pages, mainly abstracted from Smollett, on the experiences of surgeons' mates, and some particulars of the uniforms of medical officers. No generally readable work on the medical and epidemiological side of life in the Navy had appeared until now; Dr. R. S. Allison's book, while not too technical to be good reading for a sixth-form boy, will deeply interest a clinician or epidemiologist. It richly deserves Surg. Vice-Adml. Sir Sheldon Dudley's characterization as a "scholarly and fascinating story of the sea."

Killing sea diseases in order of importance numerically have been scurvy, typhus, malaria, yellow fever, tuberculosis. The second and last of these were of equal or greater importance to English landmen in old days. Now tuberculosis alone is a redoubtable foe of seamen. Dr. Allison shows that scurvy, certainly, and typhus, probably, were not characteristically sea diseases at all before the 16th century, because the technique of shipbuilding and navigation had not reached a standard permitting a ship to remain continuously at sea for months. This is, of course, a conclusive explanation of the absence of scurvy. Whether the closely packed slaves in the old galleys died of fevers or of what fevers they died we do not know. With the coming of ships able to keep the seas for long periods scurvy became a reigning plague, and so long ago as 1601 a captain—James Lancaster—demonstrated the value of orange juice. The story of the conquest of ship scurvy, of the individual and official, which had to be overcome, has been told but never better than by Dr. Allison.

The changes in shipbuilding which provided a terrain for scurvy also favoured typhus; there was less ventilation and more overcrowding on board. The British system of impressment for the Navy was epidemiologically a perfect vicious circle. The poorest and dirtiest of the population were brought into the ships and, to prevent desertion, kept on board. Typhus continued to be a sea disease almost down to a time covered by the lives of men still living. Recruitment of volunteers, a general higher standard of cleanliness within and without the Service, extension of the age-long naval demand for order from guns, decks, and rigging to the bodies and clothing of the crew, eradicated typhus.

Dr. Allison has not only given us an epidemiological history; he has told us how the Naval Medical Service grew from a mob of despised underlings, whose status and characteristics were not exaggerated out of all resemblance by Smollett, into the efficient and honourable corps we know. He has given us vivid accounts of the careers of the men—Lind, Trotter, Blane, and others—to whom we owe great reforms. Dr. Allison quotes some of the earlier vital statistics of the Navy, particularly those of Blane; it may interest the reader to supplement these with data collected by W. B. Hodge and published in the *Journal of the Statistical Society* nearly 90 years ago (Sept., 1855). Hodge, using Blane's data, estimated the mortality

rate from "diseases and ordinary accidents" in the Navy in the war years 1810-12 as 38.3 per 1,000 of strength. In the peacetime Navy of 1830-6 the death rate from all causes was 13.8 and from diseases, 11.8 (the rates for 1936 were 2.0 from all causes, 1.4 from diseases alone). He concluded that the wartime surcharge was not less than 16.0. He estimated the whole cost of life of the great war 1793-1815 to the Navy to be about 63,000 lives lost, of which 44,662 were due to excess mortality from disease. The estimated loss of lives from all causes in the Navy and Mercantile Marine in 1914-18 was 48,000. These figures illustrate the enormous hygienic improvement which has been effected. If it be objected that the modern war lasted four and the old war more than twenty years, we must remember that the average seafaring population at risk in 1914-18 was far greater than in 1793-1815.

Dr. Allison has done a national service. There is room for a good deal more research into naval vital statistics, but he has provided an epidemiological-sociological foundation for his successors.

SYMPTOMATOLOGY OF CEREBRAL DISEASE

After-Effects of Brain Injuries in War: Their Evaluation and Treatment. The Application of Psychologic Methods in the Clinic. By Kurt Goldstein, M.D. Foreword by D. Denny-Brown, M.D. (Pp. 244. 21s.) London: William Heinemann, 1943.

Among those interested in the symptomatology of cerebral disease the name of Dr. Kurt Goldstein is well known. There can be hardly any contemporary publication on the subject with no reference to his work, and his terms "catastrophic reaction" and "abstract and concrete behaviour" have become stock phrases in the neurological slang. Most of Goldstein's work published during or after the last war is now difficult to obtain, and every worker interested in the subject will welcome this concise monograph, which gives his own version (often misquoted by others) of his experiences and the theories he based on them.

Goldstein's fundamental merit was the introduction into clinical practice of modern (*Gestalt*-) psychological methods, and accordingly the chapters on the basic approach, the origin of symptoms, the psychological laboratory investigations, and the (psychological) treatment of aphasics and of patients with circumscribed cerebral defects are the most stimulating and the most valuable parts of the book. In the chapters on general and neurological symptomatology one realizes too often that the development of neurosurgery and of some auxiliary medical sciences has made much of the experience of the last war obsolete. Ventriculogram and EEG are not mentioned; methods of studying the autonomic disturbances are not up to date. The psychological part also shows some disappointing omissions, apparently due to the fact that the author keeps too closely to his earlier (1919) book. Very little is said about controls or standardization of the psychological tests used, and, more disappointing, the sorting tests with which the author's name is closely linked do not appear at all in the chapter on laboratory investigations, and are dealt with elsewhere only in a short paragraph and a reference to another publication.

DERMATOLOGY AND SYPHILOLOGY

The 1942 Year Book of Dermatology and Syphilology. Edited by Fred Wise, M.D., and Marion B. Sulzberger. (Pp. 664; illustrated.) Chicago: The Year Book Publishers.

This is the second number of the *Year Book of Dermatology and Syphilology* to be published since the war came to America, and as might well be expected the imprint of war conditions on this excellent summary of the twelve months' work reviewed is very apparent. The editors point out that in the actions of modern warfare no less than 60% of all casualties are often of the nature of burns, and consequently they devote an introductory article of some twenty pages to the treatment of burns, in which all the most modern methods are described and compared. The editors remain strongly in favour of tannic acid preparations, while excluding their use from those situations where their employment may lead to contractile scarring, disfigurement, and loss of function—i.e. on the face, hands, feet, genitalia, etc. They do, however, also commend the saline and sodium bicarbonate methods in certain circumstances and also the application of vaseline tulle gras. This chapter is too long to summarize here, but will

repay careful reading. Perhaps it is also owing to war conditions that the sociological aspects of syphilology are given much prominence in this volume. It may be news to many people in this country to learn that no fewer than thirty States of the U.S.A. require certificates of medical examination, chiefly aiming at preventing the spread of syphilis through marriage, before marriage licences may be issued. Most of them require a blood test. The control of venereal disease in the armed Forces of the U.S.A. has been a subject of considerable discussion, and the conclusion seems to emerge that the most important factor in reducing the incidence of venereal disease among the mobilized Forces is the abolition of commercialized prostitution by closing the houses of ill fame in the vicinity of military and naval centres.

In addition to these matters of topical interest the yearbook includes its usual abstracts of the more arresting publications of dermatological writers during the period under review, often accompanied by shrewd comments from the editors. It may again confidently be recommended to the attention of all occupied with the various manifestations of cutaneous disease.

Notes on Books

A medical man who veils his identity under the pen name DAVID BRUCE has set out some ideas for economic and social reform in a booklet entitled *The Future and the Fighting Generation* (W. H. Allen & Co.; 1s. 6d.). He is appalled at the present system of government which in face of the gravest danger in our history took no measures of defence until it was too late. "To-day we are a nation with a purpose . . . we do not need the regimentation necessary to combat the apathy in national affairs which is all-pervading in our peacetime social circles . . . is the new spirit in the land to survive?" "No more dangerous element is present in our midst than the win-the-war-first-and-then-we-can-think attitude. . . . Political history of the past twenty years is a sorry tale of government without principles—it was government by expedients." From these brief quotations it will be gathered that the author has positive views and feelings. His aim is to secure a better social order to-morrow by setting ideas in motion while people's minds are plastic to-day. To free the House of Commons from "the good party man" and "the tied M.P." he calls for a secret ballot in all major divisions, as the first step to a new and better safer Britain. Many who agree that the key fault in our Parliamentary system is the power of the central offices of the parties, which reduces M.P.s to mere ciphers, will not go all the way with the author in other directions.

Dr. BEEBE'S study of *Contraception and Fertility in the Southern Appalachians* is a statistically competent account of observations made on the use of contraceptives and the inferences which may be drawn as to their effect in limiting fertility. The data also throw some light upon the normal physiology and psychology of sexual union. There is, of course, a large "literature" of the subject; the writings of the late Raymond Pearl are well known, and this volume does not perhaps appreciably modify the conclusions to be drawn from his researches. The English reader who is not a connoisseur of statistical methods will probably find the first chapter, which describes the social-economic situation in the West Virginian coal fields, the most interesting. It is a grim story which should help both to make our judgment of current industrial troubles in the United States charitable, and, possibly, to convince us that our own industrial system does not lag behind that of our kinsmen. The book is published in this country by Baillière, Tindall and Cox at 14s.

A sixpenny pamphlet *The Beveridge Plan: A Symposium* is published by the Individualist Bookshop, Ltd., 154, Fleet Street, E.C.4. The longest of the three contributions is from the pen of Mr. James W. Nisbet, Reader in Political Economy at St. Andrews University, who appraises the plan under the general heading "Britain and Social Security," and criticizes some of its features in sober language, ending with the moral: "If all difficulties are removed, strength of character is undermined." Sir Arnold Gridley follows with a brief essay headed "Deceiving the People," and Sir Ernest Benn winds up with a discussion on some implications of the Beveridge Report, reprinted from the *Quarterly Review*. Both are hostile in the main. Sir Arnold is chiefly concerned to rebuke Press, Platform, Parliament, and Pulpit alike for misleading the Public. Sir Ernest concludes: "If a single sentence can sum up so vast a subject and such an overwhelming quantity of statistics and detail, it may be said that the Beveridge Report may extend the Social Services a little, but will certainly expand the powers of the bureaucracy a lot."

Preparations and Appliances

PLASTER-OF-PARIS WRIST SPLINTS

A Simple Technique for Reinforcement

Capt. I. H. BAUM, R.A.M.C., writes:

A medical officer attached to a general hospital often has to apply plaster-of-Paris splints to the forearm and wrist. From my own experience I believe that the simple dorsal plaster slab technique can be improved. The dorsal forearm slab as applied in most clinics, and a suggested modification, are described and contrasted in this note.

Customary Method of Application.—A roll of 4-in. P.O.P. bandage is made into a slab reaching from the knuckles to about 2 in. below the olecranon, extra layers of bandage being applied at the wrist region to provide increased stability at the joint. The hand is fully clenched to give optimum position at the wrist-joint. The slab is moulded to the back of the forearm, which is prone on a table at shoulder height. The disadvantages of this type of splint are: (1) The dorsiflexion at the wrist-joint causes transverse folds and wrinkles to appear in the plaster at this level, especially on the inner surface apposed to the skin. These wrinkles reduce the mechanical efficiency of the tubular plaster and increase its liability to crack. The ridges may cause soreness of the skin and prevent a smooth neat appearance of the finished plaster (Fig. 1).

FIG. 1.—Drawn from a discarded plaster. (Usual method.)

FIG. 2.—A, inside view; B, outside view; C, lateral view.

(2) The rough edges are unsightly and tend to fray or cut into the skin of the elbow.

Suggested Modification.—It is probable that the following technique is not new to many surgeons, but I have been unable to find references or advice as to this being the case. The dorsal slab is made as before, and the edges are "massaged" with the finger-tips to give squareness and to obviate fraying when dry. The plaster is reversed once on the table to ensure smoothness of both surfaces. The slab is then applied to the forearm and wrist. That part of the plaster over the centre of the carpus is pinched into a ridge 1/2 in. high and about 4 in. long, tapering proximally and distally. The rest of the plaster is then moulded in the usual manner (Fig. 2).

The advantages of this modification are: (1) The reinforcement against cracking: weight for weight, it is more efficient than the unmodified P.O.P. (2) The smoother and more closely applied inner surface. (3) The improved appearance.

Further modifications are as follows: First, after the first dorsal slab is applied a second slab is made, 5 in. by 4 in. by 1/4 in. (Fig. 3, A). One-fifth of the width is folded over at

FIG. 3.—Reinforced slab used as a wrist support.

FIG. 4.—Detachable plaster for fixation of thumb.

each edge (Fig. 3, B), and the groove thus formed is dovetailed on to the ridge of the first plaster (Fig. 3, C). This reinforced form of the slab may be used as a wrist support to enable a worker in heavy industry to carry on full duty with a weakened wrist-joint. The support can be removed when off duty. Secondly, for fixation of thumb by a detachable plaster a 6-in. bandage is made into a slab of required length. A longitudinal cut 2 1/2 in. long is made in line with the radial border of the second metacarpal. The radial part of the slab is fitted against the extended and abducted thumb, and two ridges are pinched up and moulded. The main ridge is over the mid-carpus, and the secondary ridge is at the angle of the thumb support (Fig. 4). This technique of buttressing an angled plaster will be found useful in the manufacture of casts at the ankle-joint. An anterior slab of this type applied to the instep serves two purposes: first, it prevents cracking; secondly, it provides a method of rapid removal of the plaster, since plaster shears are more easily inserted at the pleat.

I wish to express my thanks to Col. D. C. Scott for permission to publish this article.

THE F.R.C.S.

A CENTENARY CELEBRATION

A distinguished company, which included the Princess Royal, Ambassadors of the Allied nations, members of the Government, and High Commissioners of the Dominions and India, assembled in the Great Hall of Lincoln's Inn on July 21 to celebrate the centenary of the foundation of the F.R.C.S., at a reception given by the President and Council of the College. This coveted surgical diploma was instituted by Royal Charter 100 years ago, owing mainly to the efforts of Sir Benjamin Collins Brodie, then Vice-President of the College. It is pleasing to record that at the ceremony last week among those present was Sir Benjamin Collins Brodie, the fourth holder of the baronetcy created in 1834. Brodie, who became President of the Royal Society as well as of the College of Surgeons, described the object of the Fellowship in these words: "To insure the introduction into the profession of a number of young men who may be qualified to maintain its scientific character, and will be fully equal to its higher duties as hospital surgeons, teachers, and improvers of physiological, pathological, and surgical science afterwards."

A Message from the King

Sir ALFRED WEBB-JOHNSON read aloud the following message from the King: "As Visitor of the Royal College of Surgeons of England I wish to congratulate the President, Vice-Presidents, Council, and Fellows of the College on the occasion of the celebration of the centenary of the Fellowship. I have given me great satisfaction to learn that the Council has decided to mark it by conferring the Honorary Fellowship on several distinguished surgeons from the Dominions and Allied countries. I send my best wishes for the continued prosperity of the College, and trust that the plans for the restoration of its unique museum will be successfully carried out as soon as possible after the war." In his reply the President stated: "Your Majesty's interest and good wishes will be a great encouragement to all the Fellows of the College in the heavy tasks which lie before them. They wish to assure your Majesty that they will be untiring in their efforts to restore their museum, towards which they have received most generous promises of help from all parts of the Empire."

The Presidential Address

Beginning his address by welcoming the Princess Royal and other distinguished guests, the President went on to say that in the crisis of battle it was well to pause and dwell for a moment on our splendid heritage: "The past is always with us, never to be forgotten; and in the continual remembrance of a glorious past we find our noblest inspirations." Amenities of the College, he observed, had been destroyed by the enemy. They were therefore deeply grateful to the Treasurer and Masters of the Bench of the Honourable Society of Lincoln's Inn for putting their hall at their disposal that evening. There was much in common between the College and the Inn. Their Tudor gateway bore the arms of Henry VIII; the College had its Holbein masterpiece to remind them that Henry VIII gave them authority to take a historic step in their corporate progress. Inigo Jones had designed the chapel of the Inn and also the College's Theatre of anatomy, now destroyed. A hundred years ago the Hall had been built and the Fellowship of the Royal College of Surgeons instituted. G. F. Watts had painted the portrait of Brodie and also the fresco adorning the Hall.

Makers of Surgical History

"Let us now praise famous men, and our fathers that begat them. There be of them, that have left a name behind them, which their praises might be reported." Of such were John of Arden and Thomas Morstede. Of such were Wiseman and Cary; Ranby and Cheselden. Of such were Pott, Abernethy, Wey Cooper, Charles Bell, Hilton, Paget, and others. Of him, towering above all, were John Hunter, the founder of scientific surgery, and the immortal Lister. Of such also was Benjamin Collins Brodie, who founded the Fellowship of our College." After this gracious tribute to makers of surgical history Sir Alfred Webb-Johnson concluded his notable address stating that the College wished to mark the occasion by

the award of some Honorary Fellowships, the numbers of which on the Roll at one time must not exceed 50. They had been chosen for distinction in this way several surgeons from the Dominions and Allied countries. They had not forgotten those in the power of the enemy, but for the present their names must be withheld. "In accordance with precedent we have chosen some who are not practising surgeons, one of them being Madame Chiang Kai-Shek, in recognition of her services to humanity. It is with special pride that we add to our Roll the name of our great Prime Minister, the Right Honourable Winston Spencer-Churchill. I venture to assert that when the history of our times comes to be written Winston Churchill will be judged worthy of the same tribute as that paid to the greatest of our Fellows by the American Ambassador, Mr. Bayard, who, when addressing Lister, said: 'It is not a profession, it is not a nation, it is humanity itself which, with uncovered head, salutes you.'"

The Honorary Fellows

The awards which could be announced were: Sir High Devine, of Melbourne; Sir Thomas Dunhill, Serjeant-Surgeon to the King; Sir Humphry Rolleston, formerly Chairman of the Imperial Cancer Research Fund; Prof. A. T. A. Jurasz, of Poland; the Rt. Hon. Sir Earle Page; Prof. Nikolai N. Burdenko, Chief Surgeon to the Soviet Army; Prof. S. S. Yudin, of Moscow; Col. Elliot C. Cutler, of Harvard University; Prof. W. G. Penfield, of McGill University; Prof. Evarts A. Graham, of St. Louis; Prof. R. B. Osgood, of Harvard; Prof. N. S. Shenshine, of Toronto; Prof. Naguib Mahfouz Pasha, of Cairo; Prof. Innes Wares Brebner, of Witwatersrand University.

Those admitted as Honorary Fellows on July 21 were: Col. J. M. Holst, Consulting Surgeon to the Norwegian Army (presented by Mr. H. S. Souttar, Vice-President of the R.C.S.); Mr. Henry Wade, of Edinburgh (presented by Sir Girling Ball, Vice-President of the R.C.S.); Col. J. A. MacFarlane, Consulting Surgeon to the Canadian Army (presented by Major-Gen. C. Max Page, Member of Council); Prof. H. C. Naffziger, of San Francisco, Chairman of Committee on Neurological Surgery of the National Research Council of America (presented by Surg. Rear-Adm. Cecil Wakeley, Member of Council).

Two Russian Surgeons

It will be remembered (see *Journal* of June 5, p. 701) that under the auspices of the Medical Research Council and the British Council a group of British surgeons have gone to the U.S.S.R. on a joint Anglo-American Surgical Mission. During this visit Surg. Rear-Adm. G. Gordon-Taylor, as Senior Vice-President of the College, has admitted to its Honorary Fellowship the two Russian surgeons, Dr. Nikolai N. Burdenko, Director of the Operative Surgery Institute, Moscow University, and Surgeon-in-Chief to the Red Army, and Dr. Sergei S. Yudin of the Sklifassovski Hospital for Traumatic Diseases, Moscow. In admitting Dr. Burdenko, Admiral Gordon-Taylor said that in the years gone by the Fellowship had been presented three times to Russian surgeons—Victor Pachoutine, Nicolas Weliaminoff, and Vladimir Andrejevic Oppel. "We respect you, Academician Burdenko," he continued, "former pupil of the illustrious physiologist, Pavlov; we admire you as a great scientific surgeon and brilliant contributor to the advance of neurological surgery, but we honour you now as Surgeon-in-Chief to the famous Red Army, which has fought with a bravery and distinction that has commanded the wonder and admiration of all."

In conferring the Honorary Fellowship on Prof. Yudin, Admiral Gordon-Taylor said that they honoured him not only as a famous Soviet surgeon but also for what he had done by his publications to ensure that the contributions of Soviet workers towards the advancement of surgery should be known throughout the world. "The orbit of your surgical activity," he added, "has been vast and varied; you have made notable contributions to gastric surgery and have modified its technique; your writings on gastro-duodenal haemorrhage demand the closest attention and are of particular interest to myself, who have worked in the same branch of surgery; the numbers of patients suffering from cataclysmic haemorrhage whose lives have been preserved by your methods and your skill are impressive and convincing."

FACT AND FANCY IN POLIOMYELITIS

In no field of neuropathology has advance been more rapid than in the case of poliomyelitis, and the successive additions to our knowledge within the past few years have necessarily involved the abandonment or modification of earlier views on such subjects as the portal of entry of the virus, the site and nature of the essential lesion, and the bases of the characteristic clinical variants of the malady. These advances have been pursued with great eagerness, and it cannot be said that those interested in the many problems surrounding poliomyelitis have been unresponsive to fresh ideas. Anything that offers to increase our control over so grave and disabling a disease may be sure of the most careful and favourable consideration. Yet it is in the realm of treatment that it is always most difficult to secure the dispassionate assessment of results that is so essential to rational therapy, and it is fair to say that already the ideas and methods associated with the name of Sister Elizabeth Kenny have become matter of animated controversy. This controversy has now reached a further stage in the publication by an American orthopaedic surgeon in collaboration with Sister Kenny of a considerable volume¹ on the new concept of poliomyelitis formulated by the latter and on the methods of treatment she advocates. The book has no fewer than three forewords and a final commentary by other writers, and, even though we miss from this impressive list of names those most familiar to us among the brilliant band of American workers on poliomyelitis, it is apparent that Sister Kenny does not lack sponsors in their country. From Sister Kenny's foreword it appears that as a result of her thirty years' work as a nurse dealing with cases of poliomyelitis she early became impressed by the presence and great importance of painful spasm of muscles in cases of poliomyelitis, and by the need for measures to relieve it at the earliest possible moment. She developed her own technique of treatment, including the local application of heat and remedial exercises, and the latest improvements on these are fully described in the book. There can be no doubt that Sister Kenny brought to her work unusual energy and thoughtfulness, and we may well believe that the young patients who came under her skilful hands received a thoroughness of treatment that, in the Australian bush where Sister Kenny tells us she began her work and developed her theories, was unprecedented and gave results as gratifying to her patients and their parents as they were encouraging to herself. Doubtless many of these children have reason to be grateful to her; nevertheless it is permissible to regret that Sister Kenny was not content to remain an outstanding practitioner of her particular art, and that she has succumbed to the temptation to rationalize her methods by providing a scientific basis for them. For this difficult—and quite different—task she had not the necessary training in physiology and pathology. However, she has formulated what is described as an entirely new concept of the disease which Dr. Pohl, the principal author

of the book, says "almost warrants considering the entity a new disease," whatever this may mean. But it is clear that, whatever measures of practical benefit may follow from the use of Sister Kenny's methods, her "entirely new concept" must stand or fall on its merits as a necessary and adequate generalization of the facts, though not necessarily as these are stated by her. Her methods may well be useful but her concept erroneous. The allowances we may be disposed to make for her presentation of her concept, in view of the difficulties arising from the fact that Sister Kenny has no medical training, do not relieve us from the obligation of assessing this by the proper standards applicable to all medical theories; and that Dr. Pohl sponsors the concept makes it the more necessary to scrutinize it critically, in view of his experience as an orthopaedic surgeon.

Briefly, Sister Kenny's case is that we have all been in error in supposing that destruction of ventral horn cells in poliomyelitis plays a significant part in the production of the characteristic paralyses and disabilities of this disease, for in truth this lesion is only a minor consideration in most cases. In short, the morbid anatomy of the disease, as we know it, is largely irrelevant. Further, we have omitted to pay attention to the painful muscular spasm which for her is the most prominent and the most important feature of the illness, and in consequence we have adopted principles of treatment that are adverse to optimum recovery. According to her new concept the "primary lesion" of the disease—as Dr. Pohl has it, but as we may correctly name it, the essential clinical feature—is muscle spasm. This is not merely a transient initial phenomenon, but persists indefinitely unless treated and leads to wasting, weakness, and contracture of the affected muscles with resulting deformities. Secondary to this spasm is a condition of "mental alienation" in the muscles antagonistic to those in spasm. This shows itself as a flaccid powerlessness with loss of tendon jerks. It persists as long as does the spasm, and like this leads in the end to wasting, permanent paralysis, and contracture. Further, there are marked incoordination of muscle movements, and, last and not least, some small degree and extent of true paralysis due to destruction of ventral horn cells. Fortunately, says Dr. Pohl with an optimism few will feel able to share, this last item is rarely of any importance.

We may leave for the moment the question whether this statement correctly represents the facts of poliomyelitis clinically considered, and pass on to discuss the details provided as to the cause and nature of spasm, mental alienation, and incoordination, all of which features, we are told, have hitherto escaped the notice of clinicians. But it is when we come to grips with the new concept that our troubles begin, for the authors have not succeeded in achieving agreement on any of the fundamental points, and at times we are hard put to it to decide which to choose of the various speculations put forward. Thus, according to Dr. Pohl, the cause of the spasm is (a) unknown, (b) irritation of motor nerve cells in the cord, (c) a direct action of the virus on the muscle fibre or on the myoneural junction, or (d) anoxia of the muscle. Dr. Knapp in his terminal commentary suggests toxic changes in the muscle, anoxia of the muscle, or irritative cord lesions. Since no evidence is forthcoming for any of these hypotheses, it is remarkable that all the contributors to the volume are agreed that the known changes in the ventral horn cells are certainly not responsible. The quality of the spasm provides its own difficulties, for, although it

¹ *The Kenny Concept of Infantile Paralysis and its Treatment*. Saint Paul, Minneapolis, U.S.A.: Broce Publishing Company, 1943.

leads to shortening of the muscles and to their hypertonicity, it does not cause any exaggerated tonus in them.

Mental alienation provides yet more difficult matter of exegesis. For Sister Kenny it can be described only in terms of psychology—the mind is divorced from, and becomes unaware of, the alienated muscle—but for Dr. Pohl it is a matter of “physiological block in the motor pathway.” In fact, the authors trip lightly from psychology to physiology, from mind to matter, with an ease and an assurance a philosopher might envy, and with a naïve unconsciousness that they are doing anything remarkable. The alienated muscle is flaccid and inactive, and hangs between its points of insertion like a hammock, but yet differs from the truly paralysed muscle by the slight tonus it possesses. The muscle is normal, and is powerless only because the spasm in its antagonist renders it so; its structure and innervation are alike intact. According to Sister Kenny it is powerless “through some disorganization” which causes “an interruption of the normal flow of impulses and the patient cannot visualize in space the exact area from which an attempt to contract should materialize, and the impulses run riot, as it were.” Yet, “remembering that consciousness is born of the subconscious, I endeavoured to bring consciousness about by attempting to bombard this area with impulses from the surrounding muscles . . . I would attempt to restore the reflexes to the tendon of the alienated muscle,” using for this purpose a form of vibratory massage that, as she believed, restored what she calls “the brain path.” Turning to Dr. Pohl for light upon this passage, we learn that “alienated muscles are examples of a physiological block in the motor pathway. They have merely ceased to function and become temporarily dissociated from the nervous system by the action of disease and in some instances as a direct result of spasm of the opposing muscles. Even the tendon reflexes of such muscles disappear and the alienated muscle has the appearance of being paralysed.” For alienation, as for spasm, we are offered a wealth of explanations. They include reflex inhibition by antagonists in spasm, the action of the virus on the muscle, and also the confession that the cause is unknown. Dr. Knapp assumes the predominance of psychological factors, and finds in the fact that spasm precedes alienation a good reason for adopting this explanation.

The incoordination of muscle movement is attributed to “a condition in the central nervous system in which the regulation and direction of nerve impulses is upset so that the natural rhythmic and co-operative action of associated muscles is disturbed. The muscles concerned are otherwise normal, but the misdirection of nerve impulses makes muscular activity incoördinate and ineffective. The process is in no way concerned with the will or volition of the patient but is rather a disorganization of the regulating centres and nerve pathways directly attributable to the disease process itself.” These long pronouncements may be summed up by saying that alienation and incoordination are due to the disease process. They are triumphs of the *circulus in probando*, and seldom can so little have been said in so many words as these authors employ. It would be without profit to pursue this concept further. Discarding the known pathology of the disease, it offers no more than vague statements to the effect that the essential disorder is a “disruption and disorganization of the nerve cell connexions and synaptic relationships which might persist in spite of the survival or recovery of the cells themselves”—a speculation which hardly accords with the claim that

Sister Kenny's methods of treatment secure recovery in 80% of cases.

As to the facts, that some muscle spasm is an initial symptom of poliomyelitis has long been familiar, and has indeed been the basis of diagnostic clinical tests, but that it persists indefinitely unless specifically treated by hot packs and of itself leads to permanent wasting, weakness, and deformity is not the general experience. That some muscles are more painful to pressure than others is also not a new discovery, and the association of flaccid and complete paralysis of muscles with painlessness is also known. Indeed, what is characteristic is that muscles which are but relatively slightly paralysed are the most painful and tender. The statement that flaccid inactive muscles are not really paralysed, but are only alienated and lost to voluntary control, is a purely verbal distinction that lacks a corresponding reality. Indeed, the entire physiology and pathology of Sister Kenny's “new concept” uses the terminology, but does not speak the language, of science, and finds its only current parallel in the medicine of Mrs. Baker Eddy's world-famous publication, *Science and Health*.

Yet there is perhaps a little more to be said on the matter, and this from what we may surmise is Sister Kenny's own point of view. The problem of pain and tenderness in the affected muscles of poliomyelitis is one that has never been faced. It calls for some explanation, but none has ever been seriously attempted. The same is true of the tenderness of muscles in other lesions affecting the lower motor neurone, and it may be thought of as matter of reproach that we have so long evaded the questions raised by this striking symptom. That pain and tenderness in muscles add to the sum total of their weakness, and may even influence the efficiency of other muscles normally associated with them in co-ordinated movement, is possible. It is also possible that the relief of spasm and of pain by hot applications brings relief to the patient and may facilitate the use of such motor function as the muscles possess. It is further reasonable to suppose that the intensive care and superb nursing that are stated to be a part of Sister Kenny's methods will yield better end-results than the somewhat perfunctory treatment that not rarely attends the later stages of the illness in cases of poliomyelitis. But all this is a far cry from the extreme claims made for the treatment, and a matter unrelated to the theoretical concept of the disease poliomyelitis that has been built on these irrelevant considerations. Nevertheless, one can picture the situation of Sister Kenny bringing before her doctors her sense of the importance of spasm and its treatment, and finding that they were not impressed by either its presence or its importance. As a not unnatural result she has concentrated on a partial view of the symptom-complex of poliomyelitis, and has sought to force its importance, as she conceived it, upon general opinion by making it the basis of a quite fantastic conception of poliomyelitis.

It would have been better had Sister Kenny and her supporters been content to subject her methods to adequate and prolonged trial, and to have let them stand or fall by their merits. The situation has been unnecessarily and adversely complicated by the intrusion of theoretical fantasies that can only prejudice the issue. Sister Kenny claims that her concept has been accepted by the American Medical Association and by the National Foundation for Infantile Paralysis; but until the general body of authoritative opinion, so weighty in the United States, has spoken on this issue, we find it hard to believe that this concept can command any assent among those whose experience entitles them to judge.

RESETTLEMENT OF THE DISABLED

The proposals of the Tomlinson Committee, more properly known as the Interdepartmental Committee on Rehabilitation, included the scheduling of certain occupations for the benefit of disabled persons and the establishment of a register of such persons. These expedients are criticized in a memorandum issued by the Central Council for the Care of Cripples. It is contended that such a schedule and register would have most unfortunate effects, particularly in fixing attention on the disability to the exclusion of the rest of the individual. After all, the most important thing about a man who has lost a limb is not the amputated limb but the fact that he is still a man with three limbs intact, together with a brain and other valuable faculties, all in good condition if he has been properly treated while in hospital. Even the functions of his amputated limb, if the stump has been well fitted with an appliance, may have been largely restored. If, therefore, he is to be registered at all, it is misleading to take account only of the anatomical defect and to categorize him on that basis. There is something to be said for the Tomlinson proposals, which were framed to ensure some avenues of employment for the disabled: but obviously everything turns on the interpretation of disablement and on the assessment of the man's abilities apart from it. It is not enough to say that all one-armed men must be considered only for certain occupations. That would have been to exclude from his employment a former Minister of Health, not to speak of the greatest of British admirals. (Some other objections to the registration and quota system are put forward in a report presented to the L.C.C. on July 27 by one of its committees, the chief being that the quota system would carry with it the suggestion that disabled persons are a liability to the employer.)

The Central Council holds that if there must be a register it should be one of employers who have troubled to study the industrial efficiency of various kinds of handicapped workers and to encourage them. A schedule of reserved occupations for disabled persons would have the disadvantage that such occupations would come to be regarded as the proper objective for employment of such persons without regard to individual capacity or intelligence. The solution of the problem, in the Central Council's view, would be better sought along the following lines: (1) a complete health service as called for under Assumption B of the Beveridge plan; (2) an educational campaign among medical and auxiliary medical personnel and also among employers and even legislators, on the broad principles of the adaptation of medicine in industry; (3) a better service of information so that people may be more readily and expertly advised as to the facilities available for treatment, training, and employment; and (4) the replacement of the present Workmen's Compensation system by a comprehensive health service linked with such arrangements for social security as might be thought appropriate.

One direction in which the State itself might give a lead is pointed out in the memorandum—namely, by relaxing the present stringent rules for a health standard on entry to the Civil Service. Those rules were framed largely with superannuation schemes in view, so as to ensure a good expectation of life among the persons accepted; and also a low rate of sickness absenteeism. But in fact, says this memorandum, among any large group of injured persons taken two years after the occurrence of the injury the expectation of life does not differ materially from that of a normal group. As for sickness absenteeism, a large proportion of this is known to be due to minor respiratory infections, dyspepsia, and nervous complaints, to which the disabled as a group are not specially prone.

It should be added that the Central Council does not criticize in any wholesale manner the Tomlinson report. Much that the report contains it describes as sound and stimulating, and this in spite of inauspicious beginnings, for it is pointed out that the appointment of the committee was never publicly announced, and only at a late stage was the decision made to publish its report. The committee consisted entirely of members of the Civil Service, and "the conclusion appears irresistible that it was contemplated that a few civil servants should confer privately among themselves, and out of their own knowledge and experience should produce a scheme for the training and placement of the disabled." If that is so, it is all the more gratifying that the report as a whole should find favour among people of great experience in the care of the physically handicapped.

"SHOCK" FROM VENOUS OCCLUSION

Research workers are very ingenious in reproducing the symptom complex seen in man as a result of depletion of circulating blood volume and known vaguely as "shock." Not content with simple removal of whole blood or plasma from the veins, investigators have devised elaborate methods of accomplishing the same ends unlike anything to be seen in man (even in this present period of scientifically directed trauma) either in the operating theatre or on the battlefield. They then devise methods for preventing or treating the ill effects of their interference. The usual sequence is first the recognition of a clinical syndrome and then its "reproduction" in animals. Recently Phemister¹ described a case of a woman who developed "shock" with low blood pressure and haemoconcentration due to loss of 4 litres of plasma after thrombosis of the veins of the leg. This appears to be the only recorded human case of a type of "shock" analogous to that produced experimentally by Katz and his colleagues.² After ligation of the common and internal iliac veins of one side and the injection into the distal end of a solution containing carbon particles the occluded leg became swollen and cold; the blood pressure fell progressively and haemoconcentration of +40% occurred. The swelling was due to local loss of plasma, and blood also: it amounted to 5% of the body weight. The severity of this shock response could be modified and the survival rate increased from 13 to 70% by "priming" doses of desoxycorticosterone.³ By its action on fluid equilibrium the rate of accumulation of fluid locally was decreased, thus giving time for the natural compensatory processes. The haemoconcentration and fall of blood pressure after this procedure could be entirely prevented by enclosing the lower limbs and groins in a plaster cast.⁴ When the cast was removed at 36 hours the occluded limb swelled at a rate about one-fifth of that in the untreated controls and without any systemic disturbance. It is concluded that the rate of loss rather than the amount of fluid lost is what determines the genesis of "shock." The authors consider that this method of preventing "shock" by plaster casts might be used in civilian and military crush injuries (as indeed it has been by Trueta^{5,6}). It has also been shown to prevent the fatal shock following freezing of a leg in dogs.⁷ Duncan and Blalock,⁸ working along "crush injury" lines, have recommended an inflatable rubber boot, again on the basis of animal experiments. For those who have not seen crush

injury clinically it must again be stressed that "shock" in this type of case is not the immediate cause of death, except in patients suffering from other injuries and in those unable to obtain fluid replacement: these die in the first twenty-four hours. Most patients who die do so on the sixth day with a raised blood pressure and in uraemia. The clinical problem is to prevent renal damage, and it is to be hoped that this will receive prior attention from experimentalists.

THE TEACHING OF OPHTHALMOLOGY

The recent Oxford Ophthalmological Congress had a stimulating debate on education in ophthalmology. The apple was thrown by one participant who declared the teaching of ophthalmology to undergraduates to be a waste of time, because, he said, it was so rare for any of them to show interest in the subject. When they became general practitioners, he continued, they divided themselves into (a) those who sent every eye case direct to the ophthalmologist and (b) those who treated it with drops for a few days before doing so. Someone else suggested that there was a third class consisting of those who sent all eye cases to the refractonist. In the opinion of this speaker the student must have six months' whole-time work in ophthalmology if he was to gain more than a smattering of the subject, and the time should be spent under more than one teacher, so as to acquire an adequate outlook. These were extreme views and found little support from the general body of the Congress. An older ophthalmologist, with an experience of thirty years of undergraduate teaching, agreed that while the present system had brought into existence first-class eye specialists it had not produced general practitioners with an adequate knowledge of the fundamentals of the subject or even of the meaning of vision. He ascribed the trouble to the fact that the mind of the student is directed to the passing of his examinations, and naturally he devotes himself to the larger subjects, giving attention to the specialties only to the extent necessary to obtain a certificate. Another complaint is that there are few good books of ophthalmology for general practitioners, such books as are available being condensations of the ophthalmology needed by the ophthalmic surgeon, whereas the undergraduate intending general practice needs something different. One examiner for the diploma in ophthalmology complained of the general run of candidates who presented themselves. He said that many of them had no idea of how to answer a written question, having never, apparently, been taught the principles of composition at school; to draw an adequate diagram in illustration of their point was quite beyond them, and manual dexterity was poor. But, as someone else remarked, a man who can draw may be wholly unable to use the ophthalmoscope. One teacher said that he declined to teach the use of the ophthalmoscope to a student who did not possess one of his own, just as, if he were a golfing instructor, he would refuse to teach golf to anyone who did not possess clubs.

The procedure at Oxford interested the Congress. Before the war Oxford medical students took their clinical teaching in London. Now clinical training is being given at the local hospitals, where it is not fettered by tradition and long usage. The ordinary routine of the out-patient department of the eye hospital has been by-passed as likely to be of small service to those not yet qualified, who start with lectures and demonstrations in the use of instruments, practising on one another, and then are given clinical demonstrations on selected cases of the commoner conditions they are likely to meet in practice. It was the general feeling of the Congress that, whatever might be said in criticism of the methods of teaching ophthalmology or of the standard of ophthalmology in general practice, the

G.P., in this field as in others, is a key man. He is first, as a rule, to see any visual abnormality. Therefore it is essential to have properly co-ordinated teaching for his benefit. It is a question not only of the knowledge of ophthalmology desired in the newly qualified G.P., but of the knowledge of general practice desired in the specialist, into whose hands, mainly, the teaching of medical students is committed. In an ideal medical world every consultant would have had some first-hand experience of family doctoring; but, as things stand, it is difficult for most of those who are going to become specialists to pass through a period of general practice without missing the appointments they might otherwise expect. Advanced training in any direction is bound to be through specialties, but in order to counteract the evils of over-specialism some form of co-ordination must be worked out—the kind of teamwork which has already proved of such use in research and in other fields of medicine.

MALNUTRITION IN CEYLON

"Spicy breezes" do not bring the gift of health to Ceylon. The infant death rate among the non-European population is nearly three times and the maternal death rate nearly five times that of England and Wales. Moreover, poor stature and physique abound. That this low physical condition is due to a dietary rather than to a racial factor is shown by an illustrated pamphlet entitled *Nutrition in Ceylon*, published by the Society of Medical Officers of Health in the colony, which mentions that, while the children of the poorer classes are small and stunted in growth, the better-to-do are tall and well built, so that there is nothing inherent in the Ceylonese to assign him a low physical standard. Surveys of the poorer class of school children reveal that 7.7% of them are afflicted by "sore mouth," a manifestation of riboflavin deficiency, and 29% by a skin eruption known as phrynodema ("toadskin"), due to want of vitamin A. Keratomalacia is also a serious affliction among infants and young children, and two-thirds of the many blind children in Ceylon are said to owe their blindness to that cause. A dietary survey carried out in a rural population has shown that 39% of families got less than 2,000 calories per adult unit per day. The diet of the Ceylonese is also ill balanced, containing too few pulses and vegetables and too little animal food. The absence of animal food seems curious in an island with a coast renowned for its abundance of highly nutritious small fish. The Ceylon medical officers are content to state the position: they make definite recommendations, some of which call for the attention of the Government. They urge that rice, the staple diet, which now supplies about 70% of the total calories, should be supplemented by wheat, maize, and millets; also that pulses, sweet potatoes, and yams—all readily grown in Ceylon—should be more used, that more fish should be sold, and more milk provided for young children, while buffalo milk in the form of curd for older children and adults. Attention is also drawn to the importance of education and to the nutritional needs of the expectant and nursing mother and the school child.

Drugs, medical, surgical, and hospital supplies of all descriptions are urgently needed for China, who has five million men in the field and an immense amount of sickness with which to contend owing to the alarming spread of contagious diseases. The Ministry of Shipping provides the necessary shipping space and Lady Cripps United Aid to China Fund is appealing for help in supplying the things, of which our gallant ally is so short. A collecting centre at 121, Westbourne Terrace, London, W.2, has been opened, and shipment of drugs and medicines has already begun. The headquarters of the Fund are at 57, New Bond Street, W.1.

RESUSCITATION WARD IN AN E.M.S. HOSPITAL

BY

DANIEL LAMONT, M.B., Ch.B., F.R.C.S.E.

Interim Surgeon-Consultant, County of Zetland

This description of the accommodation provided for severe war casualties is submitted in the hope that it may be of interest to those who, like myself, have to treat patients suffering from exposure as well as wounds. The layout of the ward is the result of three and a half years' experience of treating such patients, many of whom are, literally, brought straight out of the sea. At one time, before Norway and Denmark were overrun and the then neutral shipping was being constantly attacked, the most appalling injuries were encountered in seamen of diverse nationalities. There might be injured Norwegian, Arab, Greek, Finnish, Swedish, and Icelandic nationals all in one ward at the same time.

When a Danish vessel was torpedoed in the Atlantic on a wild January night in 1940 the chief engineer was blown out of his engine-room when the first torpedo struck, and blown back inboard by the explosion of a second; then part of the cargo fell on top of him. By this time he had sustained compound fractures of both lower limbs, crushed thorax, and fracture of the ribs. He took to the icy sea, where, supported by his life-saving jacket, he was immersed for two hours before being picked up. After a voyage in a small storm-tossed vessel he was landed without the aid of any stretcher at a port on the west side of the Shetland Isles. Before being rushed to hospital he had to be questioned by the intelligence authorities. (However undesirable this may be for a shocked patient, it is necessary; in this case the safety of other ships was involved.) This man survived, but that is more a tribute to his own vitality than to any resuscitative measures, although skilled nursing, which is a vital factor in all shock cases, played its part.

Again, six Arabs, members of the crew of an oil tanker, were adrift in a waterlogged ship's boat for ninety-six hours; all of the men were suffering from petrol-burn injuries, more or less severe, and were without drinking-water. A child on board was supported on the knees of each of the men in turn to prevent her from being drowned in the bottom of the boat. In their case resuscitative measures were the clamant need. A Norwegian seaman escaping from Norway after we came away from Narvik was five days in the sea after his *skøyte* (small fishing vessel) was sunk under him. On being rescued he insisted on accompanying a unit of the Royal Navy to direct this craft to where he had last seen his skipper clinging to a piece of wreckage. During this venture he was shot through the abdomen by a marauding Heinkel. The skipper was found, and the Norwegian sailor had six lacerations of the small bowel repaired when his abdomen was subsequently opened. He now wears the Royal Norwegian Order of Saint Olav.

A pilot of the R.A.F. engaged in air operations during the Vaags combined operation had his left femur shattered by "flak" entering the bottom of his aircraft. In the course of his "evasive action" he struck a rock and the starboard air-screw went out of action. He kept air-borne on one engine for some hundred miles and then came down in the sea. He was picked up, more dead than alive, by the Air-Sea Rescue Section. On admission to hospital gangrene of the limb was already starting. An example of aggravated injury was provided by a sturdy young Westphalian, an *Unteroffizier* air-gunner whose pilot was forced to "crash-land" on an isolated island in the ocean. On making a "pancake" landing the bottom of the aircraft was smashed in, killing the remainder of the air crew and pinning the air-gunner in the wreckage, his lower limbs being severely lacerated and fractured. He was extricated and brought to hospital by a Royal National Life-Boat Institution vessel, which made a ninety-mile trip in a heavy beam sea to effect the rescue. He was suffering from surgical shock, intensified by bad sea-sickness and terror at what lay ahead; before his enforced descent he had succeeded in killing by machine-gun fire the wife and daughter of the islands' light-keeper. The number of such examples of injury *cum* gross exposure is legion, but arising out of these experi-

ences a technique has been evolved for giving the most effective restorative measures with the least possible delay.

General Plan and Equipment

The solutions carried on the dressing trolley may not find general acceptance, but security reasons preclude a free discussion of my choice. Suffice it to say that the types of wounds now being encountered necessitate a preparedness on the part of the surgeon to cope with injuries contaminated by a variety of chemicals, of which phosphorus is but one; picric acid is another. My rule is, when there is an element of doubt, to use distilled water for irrigation of contaminated wounds, particularly those of the eye, until such time as I can have expert guidance from the Ordnance Department, who have at all times shown their readiness to co-operate by providing the services of an analytical chemist.* Apart from that, the simplest materials are used in the resuscitation ward, as all unnecessary interference liable to disturb the patient is discontinued. Cases of frost-bite and of immersion leg are not treated in this ward unless there are concomitant injuries. For these vasomotor disturbance cases a special ward is reserved. In general the line of treatment is elevation of the part and abstention from all frictional treatment or application of heat. Morphine with atropine is freely given, and ultra-violet therapy or actual heliotherapy (when available!) has done good in cases where the penis is involved.

Hiccup is a most distressing symptom in recent immersion derangements, and the morphine-atropine combination appears to help. Thoracic blast injuries from depth-charge or mine explosion are treated in the ward in the sitting posture. Contrary to the experience of some, I use plasma infusion freely. Atropine is given hypodermically, and pulmonary oedema has not obtruded. The effect of the plasma is most gratifying in these profoundly shocked thoracic cases. The ward is adjacent to the operating theatre. Immediately outside the entrance is the poisons cupboard, in which are ampoules of alupon 2/3 gr., atropine, coramine, strophanthin, and eucortone. Sal volatile, a humble but very useful drug in some cases with emotional disturbance, is ready to hand. The type-testing sera and the antitetanic and polyvalent anti-gangrene sera are stored in a calor gas refrigerator outside the door. The blood bank, under the aegis of the Scottish National Blood Transfusion Association, is not far distant. A supply of tetanus toxoid for use in appropriate cases is available.

The ward is constructed of reinforced concrete and is proof against all but a direct hit.

Ward Fittings

1. Thermostatically controlled heating system set to maintain temperature of 68° F.
2. Hand-operated ventilators of "louver" pattern.
3. Electric lighting system from mains supply.

Bed Fixtures and Accessories

1. At the head of each bed on a wooden panel are: (a) Arcus quick-coupling unit connected with Heidbrink control unit attachment on oxygen cylinder of 100 c.f.t. capacity. Incorporated in each unit is a dry-bobbin flowmeter; delivery is by B.L.B. mask.
- (b) Plug for electric blanket, which is insulated from the patient by rubber sheeting; the current is switched on day and night for a few beds only when the ward is unoccupied.
- (c) Plug for aluminium radiant-heat cage with six independently controlled bulbs and thermometer; these cages are so light that any nurse can easily lift them with one hand.
- (d) Plug for hand lamp.
- (e) Bracket at approximate height of 3½ feet above receiving vein for blood-transfusion bottle.
2. Temperature-respiration-pulse chart on which half-hourly observations can be recorded if necessary.
3. Back-rest for sitting posture in thoracic cases.

Ward Furniture and Apparatus

1. Portable x-ray plant for use primarily in abdominal and thoracic wounds; this plant can also be used therapeutically, but this measure is still on trial for cases already infected.
2. Emergency accumulator light of "anglepoise" type.
3. Emergency hurricane lamps.
4. Dispensary basket for transporting bottles of plasma or stored blood from adjacent blood bank.

* Boric acid solution should be avoided in treating eyes if unknown chemicals may be present; extremely dangerous compounds may be formed.

5. Wooden arm-board for each bed for blood transfusion by the arm. The sternal canal may occasionally be used as adjuvant "slow-drip" route when veins are very collapsed and delay is unavoidable.

6. Low stool at bedside for operator (this is important, as it is very fatiguing to bend over these low "emergency" beds for any length of time).

7. Blocks 18 inches high for elevation of the foot of the bed. (These require some arrangement on the upper surface to keep the legs of the bed from slipping when the patient is restless. I have attached "U"-shaped pieces of wood to receive the bed legs.)

8. Hand-washing basin.

9. Dressing trolley, on which are carried: (a) solution of 1/1000 acriflavine rendered alkaline by addition of sodium bicarbonate; (b) solution of sodium bicarbonate, 0.5%; (c) solution of copper sulphate, 2%; (d) solution of copper oleate and trichlorethylene (still on trial for neutralization of external wounds contaminated by phosphorus); (e) normal saline (sterile); (f) distilled water; (g) albucid soluble, butyn 2%, and undine; (h) tubes of flavogel; (i) tourniquets, Esmarch's bandage type; (j) Riva-Rocci blood-pressure apparatus; (k) agglutination tubes charged with a few drops of a solution of sodium citrate 1.5, sod. chlor. 0.9, distilled water 100.0, for direct blood agglutination test; (l) insufflator charged with 3 g. sterilized sulphathiazole powder; (m) Record syringes 1, 5, and 10 c.c.m.; (n) metal and rubber catheters.

Staffing

1. Nursing staff: (A) A receiving sister and assistant nurse superintend putting the patient to bed and remove life-saving jacket and such clothing as is necessary. (B) The theatre sister and radiographer are in attendance.

2. Medical staff: (A) The receiving surgeon conducts a preliminary survey and orders immediate resuscitation methods. He decides the amount of alopon to be injected and the mode of administration. (B) The resident house-officer immediately types blood and carries out direct agglutination tests against the blood of a waiting donor or against the bank blood, whichever is to be used. He also carries out catheterization, if ordered. He may have to estimate blood pressure, haemoglobin percentage, and mean corpuscular volume in a Wintrobe tube after centrifugalization. Blood urea is estimated in a Lovibond comparator, if such investigation is ordered. This colorimetric method is sufficiently accurate for practical clinical purposes; it is also used for estimation of sulphonamide concentration in the blood. (C) A specialist anaesthetist is in attendance and is consulted on the appropriate form of anaesthesia in each case. Boyle's apparatus with CO₂ absorption attachment is mainly used, but regional anaesthesia is sometimes helpful. Pentothal is often used, but the impression here is that it is not so reliable as the evipan of former days. In this hospital the specialist anaesthetist also gives the blood and plasma infusions.

Resuscitation Procedure

As regards resuscitation measures generally, in my view the tendency is to give too much morphine to the shocked patient. In this hospital 2/3 gr. of alopon (equivalent to 1/3 gr. of morphine) is a maximum initial dose. If the patient's pulse is imperceptible at the wrist I content myself with the equivalent of 1/4 gr. or even 1/6 gr. of morphine intramuscularly to begin with. I am then guided by the patient's response to the other measures as to when and in what amount to give another injection subcutaneously (usually in 2, 3, or 4 hours in doses of 1/6 gr.). Eucortone has a limited place in conjunction with morphine in the treatment of these cases. It must be used with great discernment. If the patient is pulseless to begin with and after the lapse of an hour there is no improvement 5 minims of eucortone can be injected intramuscularly. Often the pulse will reappear in five minutes, but if it does not then no further hormone should be given. If improvement does occur a further 10 minims can be administered after another hour. The temperature then will probably rise above subnormal.

Experience has taught us to use oxygen sparingly in those patients who do not have compression-expansion lesions of the lungs. When it is employed the guide is the patient's reaction. If he is intolerant or resentful of it the flow is stopped. Oxygen has a very real value in cases in which there is a combination of gaseous asphyxia and shock caused by "near-miss" detonations. Whole blood is never given by itself to the shocked,

exsanguinated patient; if he requires blood then double the amount of plasma is administered—half before the blood and half after it. If the patient lapses into unconsciousness, strophanthin or 4 c.cm. of nikethamide (coramine) intravenously is given, mostly as a policy of despair. Artificial respiration in the "iron lung" has been tried, but it is too early yet to assess its value. It does seem worthy of further trial because the aeration of the blood is maintained so long as there is any circulation; it requires very careful synchronization in the unconscious patient, of course. The "iron lung" is brought into the ward when required.

The importance of competent nursing of shocked patients cannot be over-emphasized. Warm glucose drinks and sweetened ovaltine are used here when the alimentary tract is intact. The surgeon then carries out such local treatment as he thinks essential. Initial covering of wounds with acriflavine

Photograph, taken under permit by Commandant and reproduced by permission of the Department of Health for Scotland, shows sick-birth attendant, suffering from wounds of the thigh, in resuscitation ward; endmost blanket has been momentarily removed and shock cage transferred towards foot of bed for demonstration purposes.

combined with insufflation of sulphathiazole powder is the routine if a long interval is expected before the patient can be removed to the operating theatre. In eye injuries the appropriate irrigation is gently carried out, and if a foreign body is to be removed and difficulty is anticipated butyn is instilled to add to the comfort of the patient. Burns can be temporarily dressed with flavogel, and if they are not too extensive up to 3 g. of sulphathiazole is insufflated as a temporary measure. Most burns of the limbs will be encased in plaster-of-Paris after operation. When there is some doubt as to the cause of burns all lights are extinguished so that the presence of phosphorus may be detected; reliance should not be placed on odour, as some modern combination explosives are free from all odour of phosphorus. The surgeon personally administers the appropriate initial prophylactic dose of antitetanic and polyvalent anti-gas-gangrene sera. He finds out if he can—though it is often impossible—whether the patient has had tetanus toxoid. Thereafter he enters on the chart the further doses that are to be given and at what intervals. If tetanus toxoid is appropriate to a particular case he gives the "boosting" dose.

The patient remains in the resuscitation ward until the receiving surgeon decides that it is time for him to go to the operating theatre; the distance is short, but a shock cage, with accumulator, is carried on the trolley.

The British X-Ray and Radium Protection Committee issued its first recommendations in 1921, and revised reports followed in 1923, 1927, 1934, and 1938. The problem of adequate protection for the x-ray worker has been substantially eased by the introduction of the self-protected tube and by the "shock-proof" tube and equipment. Account is taken of this in the sixth report, which follows in the main the form of the International Recommendations, and contains a number of alterations and additions based on the experience of the British Committee and of the National Physical Laboratory. Copies can be had from the honorary secretaries of the Protection Committee at 32, Welbeck Street, W.1, or from the director of the N.P.L., Teddington, Middlesex.

COMING-OF-AGE OF HOSPITAL SAVING

The Hospital Saving Association, the great contributory organization for the London area, was inaugurated in 1922 as a result of one of the recommendations of the Cave Commission to inquire into the finances of voluntary hospitals. It was from the beginning a characteristically British blend of self-help and public service, and the double idea of saving the hospitals—for that was the original motive behind the Association and the inspiration of its title—and at the same time of ensuring hospital treatment for the contributor and his family when needed proved immensely fruitful. The H.S.A., which in its first year had 15,000 members, now talks in terms of millions. At a twenty-first birthday celebration held at Westminster Central Hall the chairman, Sir Alan Anderson, was able to announce that the contributors now number nearly two millions and their contributions weekly amount to well over one million pounds a year. Since the H.S.A. started its work over ten million pounds has been paid or set aside, for hospital services, and the total number of patient-days of hospital treatment given to its contributors and their dependants would extend over about 120,000 years. The celebration was attended by the Duchess of Gloucester, the Minister of Health, prominent representatives of the medical and nursing professions, and heads of large business concerns, including the chairman of London Transport, in which are to be found the largest number of contributors in any single employment.

The occasion was something more than an outstanding anniversary; it was a demonstration of faith in the voluntary system. As the Minister of Health said in his brief address, whatever the future may hold in store, no comprehensive service can do without the spirit which has created and sustained the voluntary hospitals. The hospitals themselves, he said, were indispensable to the services which it is hoped to evolve, and equally indispensable are the attitude of mind and constancy of purpose which have been displayed in supporting them. To mark its coming-of-age the Association hit upon the pleasing idea of making an offering to the nursing profession in token of gratitude for the services rendered by hospital nurses to its members. This took the form of a fund for providing scholarships for nurses, and a sum of just over £12,000 was handed to the Duchess of Gloucester for this purpose. The nurse who wishes to qualify for a higher position, such as that of sister-tutor for example, has to relinquish her work during her year of studies, and if she has no private means she is gravely handicapped. It is to meet such a situation that this gift has been conceived.

HARBEN AND SMITH AWARDS

At a meeting of the Royal Institute of Public Health and Hygiene held on July 8 the Harben gold medal was presented by Prof. J. W. H. Eyre, the president, to Sir Henry Dale, President of the Royal Society, and the Smith award (a bronze figure of Hygeia) to Dr. James Fenton, medical officer of health for Kensington.

Mr. W. E. Tanner, chairman of the council, in presenting Sir Henry Dale for the award, referred in particular to his work on acetylcholine, begun in 1914, and quoted the *British Medical Journal* as stating, in 1938, that the brilliant researches of Dale had helped to build up step by step a firm structure on which rested the belief that acetylcholine transmitted the effects of nervous impulses from the nerves to the organs throughout a large part of the body. He also reminded the company that in 1936 Sir Henry Dale shared the Nobel Prize (Nobel Laureateship) for physiology and medicine. He had made the laboratory his field and had always maintained that with the disappearance of the earlier separation and critical rivalry between experimental research on the one side, and empirical observation at the bedside on the other, and with the formation of a common front of advance in medical science, medicine would move towards the creation and maintenance of the conditions of health, not limiting itself to the recognition and treatment of acute or obvious failures and anomalies.

Sir Henry Dale, in response, mentioned the names of former Harben medallists, beginning with Pasteur in 1895, and Sir John Simon in the following year, and continuing with Lister, Koch, Metchnikoff, Gorgas, Ronald Ross, Sherrington, Hopkins, and others. One of the medallists was Baron Kitasato, the Japanese

scientist, who received the medal in 1925. "We should not fail to honour his memory," said Sir Henry Dale, "although his country has departed from its old traditions. Baron Kitasato worked for the health of all mankind."

In presenting Dr. James Fenton for the Smith award (an award created in memory of Sir W. R. Smith) Mr. Tanner said that Dr. Fenton had been M.O.H. of Kensington since 1920. Before that he had held appointments in Shrewsbury, Birmingham, and Southampton. He had been president of the Society of Medical Officers of Health, chairman of the Central Council for Health Education, and chairman of the council of the Royal Sanitary Institute. Reference was made to the fact that the Kensington Borough Council had established under his advice the first municipal clinic for acute (and later for chronic) rheumatism in this country, also to his good work for civil defence.

Dr. Fenton described the work he had done as team work, and said that many who had laboured side by side with him should have shared in the honour. A medical officer of health could achieve little without the support of his local authority, and in that respect he himself had been most fortunate. His local authority had enlarged his interest and stimulated him to introduce measures for the public benefit. It had also afforded him financial help in his studies of public health in America, Africa, and on the European Continent.

Correspondence

Subcutaneous Ligation of Varicose Veins

SIR.—I note with concern two recent articles in the *Journal* advocating the disinterment of the subcutaneous ligation of varicose veins from the shades to which it had been decently committed. Starting an honourable career more than 100 years ago, we find it adolescent in the hands of Davat, who in 1838 was devising ingenious methods for its application (*vide* Ochsner and Mahorner, *The History of the Treatment of Varicose Veins*, 1939). After an adventurous and popular career it was finally laid to rest when the injection treatment of veins became standardized in the present century. Nails from all parts of the world have been driven into its coffin in the shape of the recognition of the recanalization of thrombosed and ligated veins, and of the dilatation of tributaries to replace an excised primary vein. In fact, throughout the literature on the subject it is now generally agreed that in cases showing a positive Trendelenburg sign this re-establishment of circulation renders ineffective any ligation and excision of the saphenous vein below its junction with the femoral vein. In an excellent critical analysis of the results of various operative procedures, Moore and Knapp (*Ann. Surg.*, 1942, 115, 131) by not even mentioning subcutaneous ligation showed that its requiems had been said. They showed that ligation and excision of the saphenous vein actually at its junction with the femoral vein is the only procedure which gives reliable results, their best series being that in which this procedure was combined with a simultaneous injection of sclerosing fluid down the vein. Clinical experience bears this out. Any lesser procedure fails to recognize and deal with the primary cause of the condition—namely, an inefficiency of the valve guarding the upper end of the saphenous vein.

In the treatment of men in the Forces, even more than in civilian cases, the adoption of a method of treatment which is liable to a considerable number of recurrences seems to me an ill-advised policy. What if the recurrence occurs just when the man is most needed for active service over-seas? How shall we explain to him after his recurrence that a second operation is more likely to be successful than the first? In my own experience it is only in such men or in others who have come in contact with them that one meets difficulty in obtaining consent for operation. I feel that more valid reasons and very much more favourable follow-through results are essential before we revert to the procedure of subcutaneous ligation.

Dr. R. R. Foote (*Journal*, July 3, 1943) wisely refers to the subject of pulmonary embolism following operation for varicose veins. The danger of this complication does not seem to be fully recognized in this country. For instance, in Payne's comprehensive article (*Journal*, Oct. 18, 1941) no mention is made of it. Yet in Moore and Knapp's series

of 169 cases there were two deaths from pulmonary embolism, a third case fortunately recovering; whilst in 162 operations for varicose veins at the Peter Bent Brigham Hospital, Boston, between 1913 and 1921, three deaths from this cause were recorded. Pulmonary embolism is thus a very real danger, causing a mortality in these two series of nearly 2%. I therefore fully agree with Foote's conditions that in operations for varicose veins (1) the patient should be ambulant, and (2) the ligation should be at the sapheno-femoral junction—the first in order to maintain the circulation in the femoral vein, the second to avoid clot formation in the saphenous stump (a possible source of a pulmonary embolus) and to destroy unequivocally all the tributaries of the upper end of the saphenous vein.

In the ambulatory method I admit that there is a slightly increased risk of wound infection owing to movement of the dressing, touching the inside of the clothes, etc., but an occlusive dressing, such as a strip of elastoplast, applied on the table and removed only with the stitches, does much to eliminate this. In 130 cases treated on these lines I have seen no case of pulmonary embolism and only five cases in which the hospital stay had to be prolonged beyond the normal 48 hours. This, I think, largely answers Major Goldstone's observations about the saving of hospital bed space.—I am, etc.,

Southend General Hospital.

A. K. MONRO, F.R.C.S.

Lectures on Industrial Diseases

SIR.—The General Medical Council recently decided that medical students should receive training in the subject of industrial diseases. So far as I can discover systematic courses of lectures are not being provided in our medical schools. In the memorandum published in your issue of June 5 it is suggested that "when the medical school is near an industrial centre the theoretical teaching in industrial medicine, which is obviously to play an important part in future medical practice, should be supplemented by visits to neighbouring factories." But where is such theoretical teaching to be found at the present time? In most, if not all, of our teaching centres facilities for visiting factories are certainly not lacking, but the theoretical teaching is. Why this delay in establishing lectureships in this important subject? Is it that competent lecturers with the necessary knowledge do not exist? I admit that it may be difficult to find men who possess the necessary combined medical and legal knowledge to enable them to teach this subject, for a certain amount of legal knowledge is required to teach it properly. In every large centre of medical education, however, surely at least one suitable lecturer does exist. This delay in establishing such lectureships is a great mistake, as a knowledge of industrial diseases is of the utmost importance at the present time and will become of still greater importance after the cessation of hostilities. In this country we always seem to lag behind. In this instance such slowness of action is inexcusable. I sincerely trust that our teaching institutions will wake up and take some definite action in this matter, which to my mind is an urgent one.—I am, etc.,

Edinburgh.

JAMES BURNET.

Cutaneous Hypersensitivity to Sulphonamides

SIR.—I was interested to read the report of Major R. G. Park (July 17, p. 69) on cutaneous hypersensitivity to sulphonamides, and to know that others were experiencing this hypersensitivity in certain individuals.

In a busy casualty department I have used a large amount of sulphanilamide, mostly in the powder form, for dressings. Out of the many scores of patients thus treated I have had 5 in the last four months who have developed an acute exudative dermatitis. At first, not knowing the cause, the sulphanilamide powder was continued with increased amounts. This only made matters worse. On changing the dressing to gentian violet or a triple dye I found that the dermatitis quickly dried and then cleared.

The worst case was a small wound of the left palm with he weeping dermatitis extending over the whole hand. None of the patients was taking sulphanilamide by mouth, and control test applications were not carried out.—I am, etc.,

General Hospital, Rotherham.

A. W. N. DUFF.

SIR.—Perhaps a personal experience will help to give point to the excellent article by Major R. G. Park.

I underwent operation on March 22 for a fistulous condition involving a long and deep incision. The wound was left open to heal by granulation, and a packing of sulphapyridine (M&B 69) in liquid paraffin was employed. This dressing was continued daily up to May, when it was abandoned. The wound eventually healed completely in June, but an area of skin rather more than an inch wide on either side of the scar remained inflamed and intensely irritable, and itching was very general especially around the anus. A slight serous exudate persisted.

On July 14, on the advice of my surgeon, I used *pul. anaesthesin* (May and Baker) to allay the itching, it not being appreciated that I may be suffering from sulphonamide hypersensitivity. As the area continued to be inflamed I tried a dressing of sulphapyridine in paraffin. Next morning I had a violent reaction, characterized by increased and intolerable itching and a profuse exudation from the area, so profuse that pads of gamgee tissue placed over a dry dressing were soaked through. I then stopped all forms of local medication. Within 48 hours the inflammation began to subside, but at the end of this period a well-marked morbilliform eruption appeared in the palms of both hands, itching was general though not intense, and affected the face, knees, and dorsa of both feet.

At the time of writing the area round the wound is still inflamed and irritable, the papular condition of the palms has not subsided, and I have no idea how long this state of affairs will last. It was only by accident that I read Major Park's article and learnt the meaning of my condition. I felt that the general reaction was due to a drug, and I had the choice of three drugs: (a) *dettol*, as I had been having *dettol* baths; (b) *pul. anaesthesin*, used twice; (c) *sulphapyridine*, reapplied after an interval. Major Park's article gave me the explanation.

Two aspects of my case I should like to stress: (a) the profuse nature of the exudate, and (b) the inordinate redness of the area of dermatitis. As Major Park points out, such hypersensitivity may seriously limit the use of these valuable drugs and calls for investigation of the means of desensitization.—I am, etc.,

"MEDICAL."

Transmission of Kala-azar by the Sandfly

SIR.—In your interesting annotation on the transmission of kala-azar (July 10, p. 45) you refer to recent work on the breeding of sandflies. It is not perhaps generally remembered that our present knowledge of the life-history of the insect and the methods of breeding it in captivity are mainly due to the painstaking work of Whittingham and Rook in Malta between 1921 and 1923, who worked there as members of the R.A.F. Sandfly Fever Commission. Their results were published in the *Journal* in December, 1933, under the title of "The Life-history and Bionomics of *Phlebotomus papatasi*."—I am, etc.,

London, W. I.

J. J. CONYBEARE.

Oedema of Extremities at Sea

SIR.—I was interested to read Surg. Lieut. T. B. Barwell's letter on the above subject in your issue of July 17. When I was going out to South America after the last war on a trip via Panama, being very run down I indulged in the usual salt-water baths on board ship. I was much alarmed after a week of these daily baths to find my feet, ankles, and legs very much swollen and oedematous. I naturally examined my urine for albumin, but found it negative. I then began to wash myself with the basin of fresh water provided after the salt-water baths. Very shortly after this the oedema disappeared and never recurred. I drew the attention of the ship's doctor to this and he told me that he had often been consulted by passengers for the same symptoms, but he could give no explanation of the cause of the oedema. Knowing the action of a salt-free diet in reducing oedema I came to the conclusion that the effect of the salt-water baths was responsible for the oedema in my case. I used to take my bath before washing and shaving, and as the weather was very warm I did not dry my body after my bath, thinking that

the salt-water baths would in this way have a more tonic effect. In subsequent sea trips to South Africa, Ceylon, etc., I found many passengers complaining of similar symptoms, and told the ship surgeons to advise them to sponge themselves well with fresh water after their salt-water baths, and in every case this had the desired effect in curing the oedema.—I am, etc.,

Oban.

DUNCAN MACDONALD, M.D., C.M.

H 11 for Cancer

SIR.—The account of the experimental work, conclusions, and implications published by Gye, Ludford, and Barlow in the *Journal* of July 17 may be misleading to some of your readers, and some comment is necessary. The essential part of the correspondence relating to this work is therefore appended, from which it will be seen that the experimental methods used by Gye and his co-workers failed to conform to the conditions laid down.

Imperial Cancer Research Fund,
Mill Hill, N.W.7,
March 30, 1943.

Dear Mr. Thompson,

We have carried our examination of your product called H 11 and of the improved copper-precipitated extract sufficiently far to be convinced that the preparations have no effect on the growth of malignant cells. Our experiments will be carried through to completion before we publish them, but in the meantime I should be greatly obliged if you would let me have any comments on our failure to substantiate your claims.—With kind regards, Yours sincerely,

W. E. GYE,
Director.

Hosa Research Laboratories,
Sunderby-on-Thames,
April 12, 1943.

Dear Dr. Gye,

I have your letter of the 8th instant. I am surprised and disappointed to note that you have failed to obtain inhibitory effects using H 11 extract.

This work has been steadily developed over the last 12 years and some thousands of experiments in mice have been performed by various research workers (the data of which are available) demonstrating beyond all possible doubt the inhibitory action of the extract on the Twort carcinoma. On this basis it has been applied clinically, and evidence of its inhibitory action in the human subject has been produced by over 300 independent members of the medical profession.

As you know, you were asked to use the extract at the request of Sir Alfred Webb-Johnson, who suggested this procedure. I did not need to have its well-established inhibitory action tested for any other purpose, it being, I am glad to say, well beyond the experimental stage, and the proved inhibitory action on both carcinoma and sarcoma in the human being is now the chief matter on which concentration is being made.

Regarding your experiments, I would draw your attention to the following points:

(1) On the basis of your own figures that at least 24 experimental animals have been used, and that you administered the extract without interruption in the dosages stated, the amount of extract supplied to you was only sufficient for a maximum of 24 animals for 21 days. As you must know, this is an inadequate time period for the experiment, particularly in view of the focal reaction referred to in my letter of March 3. Moreover, on the same date I sent you as a guide to your work a graph showing the results obtained by us, which indicated the inhibition as marked by the 39th day. Your experiments should surely have been conducted for at least this time period.

(2) On March 17 a batch of H 11 which was copper-precipitated was sent to you and acknowledged by you on March 18. You wrote to me in a letter dated March 30 that you were convinced that the preparation had no effect on the growth of malignant cells. Thus you had reached this conclusion after the extract had been in your possession for a period not exceeding 12 days. You had therefore ignored my original statement in my letter of March 3 that "in the mouse tumour there is a steady increase in size up to about the 8th–12th day and this is particularly due to the focal reaction." Clearly no inhibitory results could possibly be shown within this time period, and yet at this point you stated you were convinced the extract had no action on malignant cells.

(3) You stated you have not used the Twort carcinoma, as in your opinion others are more suitable; and in your letter of March 30 you suggest I should comment on your failure to substantiate our claims. In my letter of March 3 I wrote, "Our experience so far as the use of the extract on animal tumours is concerned is restricted to the Twort carcinoma." Moreover, our published work

on H 11 extract has related solely to the Twort carcinoma (*Med. Press and Circular*, April 23, 1941). It is obvious therefore that the experiments should have been conducted using the Twort carcinoma. It was, in fact, your predecessor who strongly recommended the tumour to me as the most suitable for this work, and certainly the correlation between the inhibitory effects on these tumours and on human carcinoma has fully justified its use.

(4) Having found, some time ago, one of the inhibitors in H 11 extract to be beta-indol-acetic acid, we have since then increased its concentration by the addition of the sodium salt. A number of independent observers have described the inhibitory action of this substance on somatic growth and malignant growth (carcinoma and sarcoma) in rats and mice. For instance, Tanaka and Tuboi (*Gann*, 1940, 34, 346), using the same tumour as you have been using—namely, carcinoma 63—stated that this compound distinctly retarded the growth of the tumours. Again, Robinson (*Anatomical Record*, 1940, 78, No. 4, Supp., 80 (abstract No. 90)) obtained a similar result. We have been able to confirm the results of these and other workers using beta-indol-acetic acid and its compounds on Twort carcinoma. We surely have a right to assume that if the injections had been given regularly and for a sufficiently long period, according to instructions, equal results would have been obtained.

(5) You state that the injections were mostly intraperitoneal. In my letter of March 3 I stated: "We have found that 1 c.cm. of the extract intraperitoneally twice daily in mice bearing this tumour causes regression in the majority of the tumours"; and so we would naturally have expected you to have carried out the same method. The only method of injection which we have found to be satisfactory is by the intraperitoneal route, and your variable methods of injection may therefore have vitiated the whole experiment, particularly in view of the small number of animals used.

(6) You state that the injections were given without interruption. My knowledge would suggest that at least one group of injections were missed. On March 15 you wrote stating your supply was nearly exhausted, and the letter was received here on March 17. Your laboratories were immediately telephoned and we were informed that you were without any extract at all.

(7) As regards the tissue-culture work, the question is not whether H 11 extract inhibits tissue culture but what is the concentration at which it does not inhibit growth, owing to the concentration of total solids. Obviously any extract can be sufficiently diluted to produce no effect, and, conversely, in the case of an extract such as this, any concentration above a certain value will inhibit. To state that the extract had no inhibitory action *in vitro* would be meaningless.

Your experiments having failed to conform with the conditions for the use of H 11 extract as outlined in my letter of March 3, I am quite prepared, should you so desire, to let you have further supplies for you to use on Twort carcinoma within the conditions laid down, when there can be no question that inhibitory effects will be shown.

In the meantime, my invitation contained in my letter of Feb. 5 is still open, and if you can find time to visit our laboratories the whole of our data is open for your fullest inspection and investigation.—Kind regards, Yours sincerely,

J. H. THOMPSON,
Director of Research.

No further correspondence having been addressed to us by Dr. Gye we were quite unaware of the present communication made by him. Several new facts now emerge from it to which attention is drawn.

(1) The chart of tumours demonstrates a definite growth inhibition as a result of administration of H 11 extract when assessed by the formula given in a paper from the Royal Cancer Hospital (Free) by Boyland (*Biochem. J.*, 1940, 34, 1196).

Ratio: $\frac{\text{Growth rate during second and third weeks}}{\text{Growth rate during first week}}$

Treated Tumours	Control Tumours
1. 0.92	7. 1.5
2. 0.73	8. 1.7
3. 0.99	9. 1.9
4. 2.3	10. 0.8
5. 0.21	11. 15.0
6. 0.77	12. Regressed

Tumour size used in these calculations is the square root of tumour area. This corresponds to the "average tumour diameter" used by Boyland. The figures show that during the second and third weeks the treated tumours grew at a slower rate than during the first week. The control tumours grew nearly twice as fast during the second two weeks as during the first week.

(2) Multiple tumours frequently grow at a rate considerably greater than that of single tumours—a rate we have often found to be more difficult to inhibit by the usual dosages of our extract. It is therefore surprising that Dr. Gye should draw far-reaching conclusions regarding the effect of an extract on experimental tumours when, of the twelve mice used, one carried a regressing

tumour while seven of the remainder had double tumours. Of the six treated animals five carried double tumours while the remaining double tumour was the most rapidly growing tumour in the control group. This was an unfortunate selection, but in these laboratories conclusions would not be deduced from an experiment in which the treated and control groups differed so greatly.

(3) The authors have assessed the health of the mice by weight, changing the method of or stopping injections when "the weight of a mouse began to drop"—whatever that ambiguous expression may mean. At this critical juncture the authors laid aside the prescribed method of injection. The soundness of this procedure when investigating growth inhibitors is open to grave doubt.

(4) No information has yet been obtained to indicate the correct dosage, method of administration, or period of time required to produce inhibitory effects on tumours in animals other than the Twort carcinoma. Incidentally, the statement that "intraperitoneal injection of 1 c.cm. twice daily becomes an ordeal for a 20-g. mouse" is absurd. In these laboratories during the last three years we have injected thousands of mice intraperitoneally with 1 c.cm. twice daily without ill effect. There is no indication that the control mice were injected with equivalent dosages of saline, as they should have been.

(5) In the tissue-culture tests 50% H 11 killed both normal and malignant cells. In 10% H 11 growth rates were equal. The authors fail to record the results with intermediate concentrations, if, indeed, they were tried.

The conclusion was thus reached that the extract had no specific inhibitory action on the growth of tumour cells; certainly no such claim has ever been made by these laboratories. Whatever theory of growth inhibition is held, such an inhibition need not necessarily be accompanied by a cessation of repair processes, as was suggested in your leading article. Our observations have not led us to conclude that there is any "inhibition of growth of skin and hair and of blood cells" when physiological inhibition is at its maximum—namely, following the not uncommon phenomenon of puberty. This fact has apparently been overlooked both by your leader writer and by Dr. Gye himself (*Lancet*, March 14, 1942).

The author of your leading article evidently appreciates our theoretical basis whilst Dr. Gye and his colleagues clearly fail to do so. Nevertheless, your leading article, accepting unreservedly the conclusions of Gye *et al.*, uses them as a criticism of our research. Perhaps the author of your leader should have studied the latter results more carefully, and Dr. Gye might well have investigated our data as he was invited to do.

The fact remains that the tissue-culture experiments did not have controls, since no cultures of normal and malignant cells without H 11 extract were made. Although Gye *et al.* thought it necessary to devote the first half of their article to a description of the care and control employed in their routine methods, yet the remainder of the communication is a demonstration of the failure to employ the necessary conditions laid down and to provide proper scientific controls.

As regards the heavily biased statements made in your leading article we would only at this stage refer to the following important factors:

1. The 51 cases treated at Kingston County Hospital are all described as "advanced . . . usually in poor health . . . with few exceptions they were cases in which operation or radium therapy was considered to be insufficient to eradicate the local disease." Bearing these facts in mind, we suggest a more careful study of the details of the cases presented.

2. Our evidence indicates that H 11 extract, whilst inhibiting growth, does not interfere with repair processes. It will be noted in this connexion that Case 26 is chosen rather than, say, Case 25 or Case 37, although both the latter, having received many more injections than Case 26, are therefore better examples of the argument put forward. But perhaps the writer of the leading article preferred to emphasize a case which, according to Kidd, did not respond to H 11 extract, rather than cases described by Kidd as now "N.A.D. . . general condition very good, no symptoms, no signs of recurrence."

3. There is abundant clinical evidence in data at these laboratories fully substantiating the one and only claim made—namely, that H 11 extract does inhibit tumour growth. The data are open for any qualified persons to investigate, and full investigation has been repeatedly invited.

No claim of "cancer cure" has ever been made by us, although it is true that some cases of histologically proven carcinoma have completely recovered, all tumours having regressed. A comparatively short time period is sufficient to

demonstrate the inhibitory effect, and the statement that "eighteen months is too short a time to reach a firm conclusion that a treatment is of value" is irrelevant. As regards the supposed "fallacy of correlating the growth of oat seedlings with the growth of cancer," attention is drawn to the fact that beta-indol-acetic acid, a known constituent of urine, is an inhibitor of the root growth of plants, somatic growth in animals (Robinson, *Anat. Rec.*, 1940, 78, 166), and of carcinoma and sarcoma in animals (Tanaka and Tuboi, *Gann.*, 1940, 34, 346; Robinson, *Anat. Rec.*, 1940, 78, 80; and others).

The Hosa Research Laboratories operate under a registered charitable Trust and are thus debarred from making profit.—We are, etc.,

J. H. THOMPSON.

R. FORBES JONES.

Sunbury-on-Thames.

* * In view of the criticisms of Prof. W. E. Gye contained in the above letter we have thought it right to submit a copy of the letter to Prof. Gye so that his answer may appear parallel with it.—ED., *B.M.J.*

SIR,—We are obliged to the Editor for the opportunity of reading the communication of Mr. J. H. Thompson and his colleagues. To us the relevant fact is this: that malignant tumours of mice which we have treated with H 11 continued to grow and killed the mice at the same rate as our untreated controls. Our experiments therefore compel us to conclude that H 11 has no inhibitory action on malignant growth. So far as we are concerned, no calculations, arguments, or complaints alter this fact.—We are, etc.,

Imperial Cancer Research Fund,
Mill Hill, N.W. 7.

W. E. GYE.
R. J. LUDFORD.

SIR,—The papers by the Imperial Cancer Research Fund workers and Mr. H. A. Kidd and your leading article in the *Journal* of July 17 are of great importance. I have no direct or indirect interest of any kind in Mr. J. H. Thompson's work but have had the opportunity in the last three years of seeing something of it. I would, therefore, venture one or two comments.

Even the papers you publish seem to me hardly to justify the wholesale condemnation of your leader. Eleven of Mr. Kidd's cases (Nos. 4, 17, 20, 22, 25, 27, 29, 31, 37, 39, and 40) suggest that the exhibition of H 11 might have exercised some influence. Can further light be shed on this by the comparative analysis of a similar series of cases treated by palliative or radical surgery and/or radium? The experience of our clinicians who have used H 11 in the last two years would also be of value.

As you point out, Mr. Thompson emphasizes, that orthodox methods of treatment should always be used where applicable, no vestige of a claim is made that at present H 11 is a comparable alternative. Whether it ever will be can only depend on observation of its effect on inoperable or recurrent cancer together with the usual laboratory investigations. Prof. Kidd's work on this aspect of H 11 is obviously not encouraged but Mr. Thompson will perhaps adduce his own work on treatment of the Twort carcinoma in mice. In the mean time H 11 cannot be said to militate against the proper treatment of any case of cancer.

Your own observation that H 11 should have some effect on the growth rate of skin and hair is eminently reasonable. Some facts on the rate of growth of the nails and hair in patients treated with H 11 as compared with the normal would not be difficult to secure.

Mr. Thompson is not the only worker to call attention to the presence of growth-inhibitory substances in urine. In fact, Mr. Kidd's paper includes references to some of our work on this subject. It would be a great pity if views on this aspect of the matter prevented investigation of the existence and physiological properties of these growth-inhibitory substances. Their application to the treatment of cancer, however dramatic and whether it proves well founded, is only one aspect of the larger question. I hope that articles will not inhibit interest in growth-inhibitors.—I

Town Hall, Fulham.

J. A.

Bran in the Diet

SIR.—By the introduction of roller milling and of white flour people have been robbed not only of the vitamins and mineral of wheat but of the natural means of moving their bowels. Hence the vast sale of unnatural means of purgation. The Russians work and fight with splendid energy on wholemeal bread and cabbage soup. The scientific advisers to the Ministry of Food have added to the war loaf, as they say, all that is digestible in wheat, but have left out of account the important natural purgative effect of bran. A finely milled whole-wheat loaf is much tastier than war bread; but the millers want us to go back to white bread after the war, and secure again the great profits made from milling—profits which have been made to the detriment of the people's health. The almost universal decay of teeth is one result, and a proper diet, not dentists, will remedy this.—I am, etc.,

Chalfont St. Peter.

LEONARD HILL.

Shortened Puerperium

SIR.—I have read with much interest the letters upon this subject in your issues of May 22, June 5 and 19, and July 3 and 10. In this correspondence too little reference has been made to the interests of the children concerned. The younger children, no less than the elder, of a family require nine months' abundant breast-milk feeding given by an unfatigued mother. This feeding is best secured, as family medical histories suggest, by a four-weeks puerperium with subsequent domestic help for the mother.

Often to-day, of necessity, the "monthly nurse," succeeded by the "nurse to take the baby from the month," must be replaced by a three-weeks stay in a nursing-home (followed by the kindly domestic help of friends) for the mother. Many doctors, I feel, would gladly further a plan, if formulated, by which a four-weeks puerperium could be secured to the average mother so that her infant might the better thrive. The financial cost entailed could well be defrayed by the money mistakenly spent in supplying non-breast-milk and bottles to infants, while attempting the restoration to health of their unrested mothers.—I am, etc.,

HELEN YOUNG.

SIR.—I have been interested as a medical woman in the correspondence about shorter puerperium.

After observing the activity of many African women as early as the day of delivery and the absence of ill effects, it seemed to me reasonable to have a shorter puerperium than the generally approved ten days. After the birth of my first child I got up for a short time on the third and on each succeeding day. There was considerable perineal discomfort, which persisted for at least a month. There had been a second-degree tear and some local sepsis in the wound.

After the second child, two years later, when there was no tear, I got up from the second day onwards for hot baths (at 100° F.) and exercises of chest and abdominal muscles, and gradually progressed from a walk round the room on the 2nd to a routine of easy activity on the 10th day. Fitness at this stage was certainly beyond what one had observed among patients during a term as resident in a maternity hospital. The same procedure was followed after the third confinement, also with excellent effect. On no occasion was there any rise in daily P.T.R. readings.

The conclusion I think is that the symptoms of the patient are a safe guide, that there should never be any feeling of strain, but that, after an uncomplicated delivery, early baths and exercise short of producing fatigue are valuable in restoring muscle tone, regulating milk supply, and avoiding the usual weakness resulting from a longer period of recumbency.—I am, etc.,

Beverly, Yorks.

ADELE NYE, M.B., CH.B.

Obstetrical Forceps for Fibroid

SIR.—On reading the interesting memorandum by Mr. John Stallworthy under this heading (July 10, p. 41) I was reminded of a similar case which occurred in my practice in Midlothian forty years ago.

A coal-miner's wife aged 46 was seen by me as she was having uterine haemorrhage. The bleeding had come on a few days pre-

viously, and was not excessive. The history was that there had been similar attacks, occurring at irregular intervals, each lasting for three or four days, for about four months. She had been an in-patient at a hospital for the same symptom some months before I saw her.

The patient was of good physique but very pale and anaemic. The uterus was the size and shape of a 34-months pregnancy, but there were no corroborative signs of this condition. Per vaginam the os uteri was an inch in diameter, and protruding through it was a lobulated mass, much firmer and more fibrous than a placenta. The diagnosis was a submucous fibroid in process of extrusion.

Liquid extract of ergot π , xxx t.i.d. was prescribed and anti-septic douches ordered. The haemorrhage stopped and did not return. In a few days the mass protruded fully an inch beyond the os. At the end of ten days the mass had descended to within an inch of the vulva, and the cervix could no longer be felt. During this period an offensive discharge was present, with occasional slight rise of temperature, and there were other indications of toxæmia—namely, an ashy-grey colour of the face, and the pulse was quicker than normal and of small volume.

As at the end of this time the patient's condition was not good, chiefly because of toxæmia due to want of drainage of the uterine cavity, it was obvious that the tumour must be removed. She was given two ounces of whisky to drink instead of an anaesthetic, put into the left lateral obstetric position, and Milne Murray's axis traction forceps were applied to the tumour (which fitted them neatly). Moderate traction failed to bring it down, so the forceps were rotated through three-quarters of a circle in order to tear through the pedicle. The whole tumour then came out quite easily with very little haemorrhage. A strip of gauze also came out with the tumour, this having probably been left in the uterus from some previous plugging for haemorrhage.

The tumour had undergone fatty degeneration in parts, and was slightly smaller than a baby's head. The attachment to the fundus uteri was flat and about nine square inches in area. No other fibroids were present. The patient made a good recovery.

—I am, etc.,

Bridgewater.

JOHN H. AYTOUN, M.D., C.M.

The Cult of Negative Health

SIR.—I am indebted to Dr. Pegge for pointing out that my letter of June 19 might be used as an argument against social planning. I imagine that Dr. Pegge had in mind the possibility of its being suggested that I had advocated any kind of work, however boring and fruitless, as a means of avoiding mental ill-health. This was certainly not my intention. The factory hand on a routine job and the working-class mother whose only tap and sink are at the end of the court necessarily have most of their energy used up on a few monotonous activities, but this is emphatically not an environmental situation which demands or even gives opportunity for the use of all their "interests and abilities" as distinct from sheer physical strength. Moreover, this extreme canalization of activity into repetitive tasks inevitably encourages and increases man's lack of awareness of his powers, while at the same time giving him very good grounds for believing that "work" is invariably distasteful and dull. Where the environment stimulates activities, forgotten or unknown powers and interests are discovered. The man of all-round training who has enjoyed the use of many and varied abilities may continue to seek means of employing them under restricted conditions. Where, however, there is a lack both of environmental stimulation and of self-knowledge it is obviously impossible for the individual to get out of the rut unaided. It is this situation which, as Dr. Pegge says, calls for social planning applied to the whole field of human activity.

Nevertheless, at the risk of confusing matters, I feel obliged to say that, if we are to believe our patients, it would seem that any work is better than none. In support of this, I would like to quote an intelligent young woman seen in consultation since my last letter. She has been ill for over two years with acute fears concerning her own body. She has always been physically healthy and has had no previous breakdown.

"I had been a weaver for five years and I had worked my way up until I was weaving worsteds. But I found that was very easy work. The machines look after themselves. I didn't like that. I got very self-conscious—with an idle mind. So I got out of it and went into war work. But no work came in. I had nothing to do for five months. I didn't get my cure—hard work. We had to sit by the machines all day, not reading or knitting. We mustn't

do anything, because, when the manager came in, he had to see that we were willing to work. Then I couldn't eat or sleep and broke down. I've a lot of energy and I ought to be kept occupied."

One could hardly have a better description of the ills wrought by over-investment of energy within the individual owing to refusal of the environment to permit any outlet. The grim irony of a situation in which readiness to work is judged by willingness to remain idle was, I may add, quite unrecognized by the patient.

The thoughtful contributions of Dr. Maberly and Dr. Eates have opened up the subject considerably. Dr. Maberly's comment on the increase of hypochondria and anxiety states during a period in which physical health and economic security have improved is entirely in line with Lord Geddes's observations and my own. It comes to this: although we should like to think that we are rational beings, influenced in our feelings, judgments, and beliefs only by present external reality, this is not and never has been so. No measure of physical or economic security bestowed upon us from without can give us the experience of happiness, well-being, and confidence which is to be gained by the full use of our own powers. That Dr. Eates considers that my "thesis deserves the closest attention" is, I suggest, an unintentional but grim indictment of our present outlook, since, far from being original, it is at least as old as our era. In my humble opinion the parable of the talents (St. Matthew, ch. 25, vv. 14-30) presents, with the utmost precision and detail, this entire problem. But how, in the present complexity of our civilization, shall we find a solution?—I am, etc.,

London, N.W.3.

R. E. LUCAS.

SIR,—I am in complete accord with the letters of Dr. R. E. Lucas (June 19, p. 766) and Dr. A. R. Eates (July 10, p. 55). I am particularly impressed by Dr. Eates's reference to "the disastrous effects upon the health of both body and mind of women who have practised contraception and the severe limitation of the family," and his statement that in his experience the most healthful women have been those with large families. With 50 years' experience behind him he will have no difficulty in proving the truth of this statement. Can Lord Dawson, Lord Horder, and the Family Planning Association as easily prove the contrary?—I am, etc.,

JANE SCOTT CALDER.

Treatment of Venereal Diseases

SIR,—As a venereologist likewise appalled by the way patients are being mistreated in general practice I found Brig. T. E. Osmond's article on the modern treatment of gonorrhoea (July 17, p. 72) very interesting reading. My experience is that the majority of these patients are treated by the medical practitioner unskilled in the treatment of venereal disease. His main aim is the acquiring of large fees, which he can both demand and get from uneasy patients by supplying the initial treatment in the easily administered sulphonamide group of drugs.

The average practitioner is without most of the expensive equipment such as incubator, urethroscope, etc., required for tests of cure; furthermore, after the cessation of urethral discharge he has neither the time nor the interest to carry out final tests of cure, and the patient is discharged under the impression that a cure has been effected. The time has arrived for some form of legislation to prevent medical men who have not obtained recognized postgraduate experience from treating venereal diseases.—I am, etc.,

IAN MCLACHLAN.

Scunthorpe, Lincs. Medical Officer of Health and Venereal Diseases Officer.

Symptomatology of Malaria

SIR,—Since you kindly published my letter on the above subject (July 17, p. 86) I have discovered that the classification of the types of malaria used in hospital was drawn up by Sir Philip Manson-Bahr in his official Army instruction pamphlet for the guidance of medical officers. The classification proved so valuable that its author should be known.—I am,

D. M. M. FRASER.

Practice and Precept

SIR,—According to Dr. Charles Hill (*Journal*, May 22) the Minister of Health proposed that general practice should be conducted on a salaried basis. According to the *Manchester Guardian* (July 13), the Minister of Health as leader of the Liberal National Party, addressing the Post-war Policy Committee, said: "I must make it abundantly clear that we attach the utmost importance to a concerted and effective attempt to give free enterprise and initiative full play in the broad sweep of all our national plans."—I am, etc.,

S. WRAY.

Whole-time Security

SIR,—Your editorial on the forthcoming White Paper advocates a background of security for the whole-time research worker, and, quite rightly, postulates that this essential security depends on the research worker living on a whole-time salary. It is equally imperative that the general practitioner has a background of security—a security lacking now, a security only possible if the G.P., like the research worker, lives on a whole-time salary.—I am, etc.,

MERVYN ABRAHAMSON.

Health Centres

SIR,—It is probable that a majority of general practitioners are opposed to the provision of these centres, but I find a few of our colleagues have failed to consider all the implications. Some regard the centres as a convenient sop to Cerberus—a minimal concession to a general ill-defined desire for change. Perhaps in others there is a hint of petticoat government. Our wives would naturally welcome separation of the practice from the household. The prestige of the Peckham experiment may influence some—though this brilliant investigation in social biology was surely never intended as a blueprint for medical practice. More regular hours of duty and holidays without the worry of a locum must also be allowed their attraction. May I beg those who have been influenced by these or other considerations to allow:

First, the tremendous cost of building, equipping, and maintaining the centres (about 2,500 of them in the whole country on a basis of 10 doctors per centre and about 2,000 patients per doctor)—plus the wasteful duplication of pathological, radiological, and other specialist services as between the centres and the local hospital.

Secondly, that no matter what the initial arrangement may be, these centres will be bound eventually to bring us partly or wholly within local government provisions—surely it would be found in practice that the only competent authority for staffing, maintenance, and finance would be the local council. And this more logically since it is obviously intended that we should discharge some part of the responsibilities of the medical officer of health—particularly in regard to maternity and child welfare, though I am sure that few of us would be willing or qualified to undertake the work and do it efficiently.

Thirdly, that the provision of the centres would mean the end of general practice as we have known it. Until the inevitable collapse of the centralization policy there would be no man among the welter of specialists, medical officers and administrators whose job would be to know the whole patient in relation to his whole environment—a fact of great significance in the present state of medical knowledge, wherein some attempt at integration of scientific findings within their sociological and philosophical background would surely prove most fruitful for future advance. It will be argued that this is too dismal a view of results, but I am personally convinced that it would work out so in practice. Mrs. A would in the first case attend her own doctor at the centre—granted. But on her return visit for observation of progress she would find unfortunately she had picked her own doctor's day off. She would see Dr. B, who might advise some further investigation. At a subsequent visit she would find her own doctor was now absent on a compulsory refresher course (pace B.M.A. and the Interdepartmental Committee on Medical Schools) at Dr. B on holiday, so Dr. C would have to start from scratch. Later perhaps her doctor would be "posted" to another centre—and so on and on.

Lastly, should we not consider the convenience of our patients? Which of our patients would not rather go round the corner and see Dr. Jones at his morning surgery and be back in time to see to the family's lunch, rather than dress up to go down town to the centre and be sorted out like sheep into the appropriate pen?—I am, etc.,

JOHN R. M. SANGSTER,
Capt., R.A.M.C.

Obituary

C. J. S. THOMPSON, M.B.E., Ph.D.

Mr. C. J. S. Thompson, who died on July 14, was born at Liverpool on Aug. 27, 1862. Educated at Liverpool University, he devoted his early days to the study and practice of chemistry and pharmacy, with a special interest in the history of both these sciences. In 1909 he was appointed Curator of the projected Wellcome Historical Medical Museum and came to London to take up his duties. From that date until his retirement in 1926 he threw all his energy into gathering together and organizing the unrivalled collection housed at that time in Wigmore Street, W. In the course of arranging many noteworthy acquisitions he travelled extensively in Europe.

During the last war Thompson raised and trained two voluntary aid detachments of the British Red Cross Society, and established the "Holmleigh" Auxiliary Military Hospital, Harrow, of which he became the commandant. Many hundreds of British wounded passed through the hospital, and on its closing in 1919 Thompson was awarded the M.B.E. for his services. In 1927 the Royal College of Surgeons of England elected him honorary curator of the Historical Section of its Museum in Lincoln's Inn Fields, and in this position he worked untiringly until the collection was almost completely destroyed by enemy action in May, 1941. Fortunately Thompson had by that time finished his work on the *History and Evolution of Surgical Instruments* (New York, 1942), which placed on permanent record some of the Museum's most important exhibits.

The outcome of a life-long study of toxicology, C. J. S. Thompson's *Poisons and Poisoners* (1931) is a standard reference work. Outstanding among many other literary excursions into the byways of medicine, chemistry, and pharmacy was *The Art of the Apothecary* (1929). Already a member of the Royal Society of Medicine, Thompson became in 1936 a Commander of the Order of the Hospital of St. John of Jerusalem. For his researches in the history of medicine he was also elected an Associate of the Royal Academy of Medicine, Turin.

Dr. INEZ MEYER (Mrs. Struckman) died suddenly at her home in West Wimbledon on June 5. She was a student of the London School of Medicine for Women and the Royal Free Hospital, qualifying M.R.C.S., L.R.C.P. in 1926 and later graduating M.B., B.S. Lond. After holding several resident appointments she started in practice in West Wimbledon and still continued at intervals to help in hospital clinical work. In both hospital and private practice her keen interest in all branches of medicine, her sympathetic understanding and friendly cheerful personality were greatly appreciated by her patients and her colleagues, who mourn the loss of an excellent doctor and a valued friend. She was a devoted wife and mother, and to her husband and two young daughters our deepest sympathy is extended.—E. M. H.

The death took place at Reading on June 30 of Dr. CAMPBELL HIGHT, late of Ayr, aged 75. After graduating M.B., C.M. at Glasgow in 1892 he started general practice at Cardonald, later moving south to Wisbech, Worcester, and Reading, where he had practised for the past 28 years. For many years Dr. Hight lectured and examined in first aid and home nursing for the St. Andrews Ambulance Association, the St. John Ambulance Association, and the British Red Cross Society.

Mr. HUGH WRIGHT THOMSON, consulting ophthalmic surgeon to the Glasgow Royal Infirmary and Ophthalmic Institution, died on June 16. He was born in Glasgow in 1873, and from Allan Glen's School went on to study medicine at the University, graduating M.B., C.M. in 1895. He proceeded M.D. seven years later, after holding a number of house appointments at the Royal Infirmary and Glasgow Eye Infirmary. Mr. Wright Thomson had a distinguished military record during the last war, serving in Gallipoli, Egypt, Palestine, France, and Belgium as lieutenant-col., R.A.M.C.(T.), in command of the Lowland

Mounted Brigade Field Ambulance. His services were recognized by the award of the D.S.O. and the Territorial Decoration, and the Order of the Nile, 3rd Class. On returning to civil life he was appointed ophthalmic surgeon to the Bellahouston Hospital under the Ministry of Pensions and medical referee for ophthalmic cases in the Sheriffdom of Lanarkshire; and was also for a time senior oculist to the Glasgow Education Health Service. He had been a member of the B.M.A. for the past 45 years.

Dr. WILLIAM ELSLIE HENDERSON, of Carlton Place, Aberdeen, died on June 26, aged 71. He studied medicine at Aberdeen, Edinburgh, and Dublin, after graduating M.A. of Aberdeen University in 1893, and took the M.B., Ch.B. Aberdeen in 1898 and the D.P.H. of Manchester University in 1911. Before entering the Public Health Service Dr. Henderson had been resident house-surgeon at the Aberdeen Royal Infirmary and surgeon to Kirkcaldy Hospital. He was for some time M.O.H. and school medical officer for the County of Westmorland, and published articles on epidemic poliomyelitis in *Public Health* and on Westmorland school children in the *Caledonian Medical Journal*. In recent years he had served as temporary assistant county M.O.H. for the Lindsey part of Lincolnshire and lived at Horncastle. He joined the B.M.A. in 1898.

We regret to learn from Trinidad of the death of Dr. EDGAR NICHOLAS DARWENT, a very old member of the British Medical Association. Born in 1864, he studied medicine at the University of Edinburgh and graduated M.D. in 1887. In Trinidad he held the posts of resident surgeon at the two hospitals, and after retiring from the Government service had a consulting practice in Port of Spain, from which he retired owing to failing health four years ago. Dr. Darwent was the first chairman of the Northern Division of the local branch of the B.M.A.

Universities and Colleges

UNIVERSITY OF OXFORD

In the Sheldonian Theatre on July 24 a ceremony was held for the second conferment of the degree of M.U.Dr. upon Czechoslovak medical students who have completed their studies in England and passed the special qualifying examination conducted by the Examining Board in England of the Royal Colleges of Physicians and Surgeons. The degrees were conferred by the Vice-Chancellor, the Regius Professor of Medicine, and the Nuffield Professor of Therapeutics in the University of Oxford, which is acting as sponsor for those Czechoslovak universities which are closed under the German occupation.

UNIVERSITY OF EDINBURGH

A graduation ceremony was held on July 14, when the following degrees and diplomas were conferred:

M.D.—Surg. Lieuts. J. J. Crawford and E. L. Thomson, R.N.V.R.
M.B., Ch.B.—T. M. Abbas, T. L. Adamson, W. R. M. Alexander, R. P. Anderson, Catherine O. Bell, W. J. Bell, G. S. P. Birrwise, J. A. P. Bouton, D. C. Boyd, Janet Bruid, J. S. Brown, S. Campbell, J. A. Caskey, Jessica B. Cores, C. M. Cornforth, B. Cruickshank, J. M. Cuthill, J. A. Dick, R. W. Drayton, G. R. H. Drew, T. B. M. Dunn, J. C. Edgar, R. Elliott, Constance M. Evans, Ida M. K. Fenton, Mary G. Findlay, J. B. Gibson, G. T. Goodall, Jessie R. Gray, Sarah K. R. Gray, H. Mack, Guthrie, R. D. Guy, R. R. Hamilton, H. C. Hastings, Lorna H. Heslop, Miriam H. Heston, Elizabeth M. Hislop, D. R. Hughes, D. Hutchison, D. G. Illingworth, W. H. Isles, Isla M. S. Jamieson, J. C. Johnson, Kirsty M. F. Johnstone (née Barker), A. H. D. Leach, J. H. Lawson, D. S. Leitch-Ross, Audrey B. Lennie, W. M. M. Lyon, Margaret MacDonald, H. A. M. Duggie, Margaret M. McIntosh, A. M. MacLachlan, A. M. Macleod, A. D. Macquenn, D. J. L. McWatt, J. G. Martin, T. S. Matheson, M. Mendick, R. C. Milne, Patricia E. Mitchell, A. H. Morrison, J. A. Morton, Agnes P. Muir, W. D. Munro, W. Murdie, Janet T. Murdoch, G. H. Pearson, J. J. Pepper, Margaret G. Proudfoot, R. J. G. Rattrie, Monica M. Renner, Dorothy C. G. M. Reside, C. Rieley, G. I. Robertson, D. W. Robinson, J. Ross, D. Savory, D. I. H. Smith, J. G. Sommerville, R. J. C. Southern, Sheena G. D. P. Spence, Sheila M. Stark, Isabel F. Sutherland, M. Tait, H. B. Taylor, G. H. M. Thornton, A. R. Watson, R. W. Watson, Margaret Watt, Elizabeth G. Watts, T. B. Whiston, J. B. Wilson, L. A. Wilson, Olive Wilson (née MacMillan), Robert D. Young, B.Sc.—Margaret G. Proudfoot, M.B., Ch.B.
D.P.H.—J. B. Brown, J. O. H. Sizze.

1 Commended for thesis. 2 In absentia.

The following prizes were presented:

Entles Scholarship and Leslie Medal, Keith Memorial Prize in Systematic Surgery, and Beane Prize in Anatomy and Surgery: H. T. G. Strathbridge. Scottish Association for Medical Education of Women Prize, Dorothy Gillies Memorial Prize, and Murdoch Brown Medal in Clinical Medicine: Elizabeth M. Hislop. Mount Scholarship in the Practice of Physic: W. Murdie. Buchanan Scholarship in Midwifery and Gynaecology: K. J. R. Cuthbert. James Scott Prize: A. C. Macdonald. Royal Victoria Hospital Tuberculosis Trust Medal: D. J. C. Cunningham. Annandale Medal in Clinical Surgery: P. M. Roome. Parton Prize in Clinical Surgery: G. V. R. Born. Wightman Prize in Clinical Medicine: C. W. Shearer. Murethorn Memorial Scholarship in Clinical Medicine: R. Cruickshank. Gunning Victoria Jubilee Prize in Zoology: D. K. K. E. Kavan. Gunning Victoria Jubilee Prize in Physiology: A. E. Ritchie. Lewis Cameron Undergraduate Prize in Bacteriology: J. M. Leland. Colonel Thomas

Biggam Memorial Medal and Prize in Pathology: J. T. Gray. *MacLagan Prize in Forensic Medicine*: I. M. Richardson. *Cunningham Memorial Medal and Prize in Anatomy*: W. R. St. Clair; prox. acc., R. B. White. *Whiteside Bruce Bursary*: Jean M. Dance. *Vans Dunlop Prize in Botany and Zoology*: D. W. Lyon and Margaret Sirling (equal).

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

At a meeting of the College, held on July 20, with Mr. J. W. Struthers, President, in the chair, the following, having passed the requisite examinations, were admitted Fellows:

C. P. Allen, G. W. Baker, D. T. Howell Evans, C. C. M. James, H. Lytton, I. S. McGregor, A. K. Mitting, James Reid, T. R. Simpson, G. F. F. Sinclair, M. Weinlos.

SOCIETY OF APOTHECARIES OF LONDON

At a meeting of the Court of Assistants held on June 22, with Sir Stanley Woodwork, Master, in the chair, Sir Hugh Lett was re-elected as the Society's Representative on the British Postgraduate Medical School; Dr. H. Seaward Morley as delegate to the Representative Committee of the British Medical Association; and Wing Commander R. R. Trail to represent the Society at the 26th Annual Conference of the National Association for the Prevention of Tuberculosis.

The following candidates have satisfied the Examiners in the subjects indicated:

PATHOLOGY, BACTERIOLOGY AND FORENSIC MEDICINE.—J. A. Baldwin, T. L. Benson, D. M. Carnegie, B. A. Gould, D. B. Lawrence, T. Moss, C. D. Sanders, R. M. B. Talbot, R. N. Thackston, W. M. Thomas, B. E. O. Williams.

SURGERY.—S. R. Abrams, A. M. Earle, P. L. G. Cole, C. M. F. Fiducia, I. D. Henderson, J. S. Pegum, A. G. M. Reese, C. D. Sanders, J. H. S. Scarlett, W. Sommer, C. T. Tahil, M. N. Tata, B. E. O. Williams.

MEDICINE.—J. A. Baldwin, R. F. Bates, T. L. Benson, D. M. Carnegie, C. M. F. Fiducia, B. A. Gould, I. D. Henderson, G. R. S. Jackson, D. B. Lawrence, T. Moss, A. M. Rajah, R. M. B. Talbot, B. E. O. Williams, S. Yaffie.

MIDWIFERY.—M. J. Beilin, C. P. Brown, J. D. Henderson, P. S. Hollings, D. B. Lawrence, D. D. Rosewarne, A. J. M. Reese, C. D. Sanders, M. N. Tata, F. R. Walker.

The Diploma of the Society was granted to T. L. Benson, C. P. Brown, D. M. Carnegie, P. L. G. Cole, P. S. Hollings, D. B. Lawrence, P. S. Pegum, A. J. M. Reese, W. Sommer, C. T. Tahil, R. M. B. Talbot, and B. E. O. Williams.

The Services

Major (temp. Lieut.-Col.) G. S. N. Hughes, I.M.S., has been awarded the D.S.O., and Capt. B. P. Tully, R.A.M.C., A. Qadir and R. S. Sahi, I.M.S., have been awarded the M.C. in recognition of gallant and distinguished services in the Middle East.

Capt. H. D. Eddy, R.A.M.C., has been awarded the M.C. in recognition of gallant and distinguished services in North Africa.

Capt. R. E. Johnson, M.B.E., and C. S. Smalley, R.A.M.C., have been awarded the M.C. in recognition of gallant and distinguished services in Burma.

Capt. E. T. Gilbert, O.B.E., R.A.M.C., has been awarded the D.S.O. in recognition of gallant and distinguished services in the field.

CASUALTIES IN THE MEDICAL SERVICES

Killed as the Result of an Accident on Active Service Overseas.—Squad. Ldr. T. D. R. Aubrey, A.A.F.

Killed.—Capt. A. O. Karstaedt, R.A.M.C.

Wounded.—War Subs. Capt. H. C. W. Baker, R.A.M.C., Lieut.-Col. J. W. Orr, M.C., R.A.M.C.

DEATHS IN THE SERVICES

Surgeon Rear-Admiral Sir ARTHUR REGINALD BANKART, K.C.V.O., R.N., died at Kenbrook, Star Cross, South Devon, on June 19, aged 74. He received his medical education at the University of Edinburgh, whose degree of M.B., C.M. he took in 1892, and in 1905 he passed the D.P.H.Lond. His efficiency is also shown by the award to him of the Gilbert Blane gold medal in 1910. As early as 1899 he was appointed surgeon in Queen Victoria's yacht *Osborne* and was transferred to the new *Victoria and Albert* yacht in 1901, on which he served until July, 1914. On the outbreak of war a month later in that year he was appointed senior medical officer to the battleship *Agincourt*, and once more proved his efficiency at the Battle of Jutland and was noted for early promotion. In 1917 he became medical officer of the Portsmouth Marine Division and in 1919 more joined the *Victoria and Albert* yacht. He was promoted to be surgeon captain in 1920 and surgeon rear-admiral in 1923, and retired at his own request in 1924. At various times he attended members of the Royal Family, and was awarded the M.V.O. in 1898, the C.V.O. in 1911, and the K.C.V.O. in 1923, in addition to being appointed as Honorary Physician to the King. In the course of his distinguished service Admiral Bankart was awarded foreign orders by Turkey, Russia, Greece, and Denmark.

Medical Notes in Parliament

DECLINING BIRTH RATE

The trend of population was debated in the House of Commons on July 16, a discussion being arranged upon the votes for the Ministry of Health, the Department of Health for Scotland, and the Registrar-General's Office. Group Captain WRIGHT, who opened the debate, said it was difficult to interest people in the subject owing to the lack of a Government population policy and the difficulty of obtaining complete statistics. Yet the trend of the population was the base on which Ministers must initiate social improvements during the period of reconstruction. The nation must have a Government population policy and more complete statistics. Britain had over 2,000,000 fewer children under the age of 14 and 2,500,000 more persons over the age of 60 than in the last war. There were 1,500,000 fewer children than at the time of the Boer War and, in fact, fewer children than in any year since 1876, when the total population of the country was 24,000,000. In 1971, though the total population would be approximately the same as now, there would be 50% more people over the age of 45 than there were to-day, and 100% more people over 65. The number of people aged 45 and under would be only 75% of what it was to-day.

The net reproduction rate showed the number of girl children who survived to replace in the next generation the women of reproductive age in the present. Since the early 1930's the net reproduction rate had been about 75%. At that rate the nation must lose a quarter of its population every generation; which could be considered as being a period of 30 years. If the present death rate of those under 45 were halved it would still lose nearly a fifth of its numbers every 30 years. By 1971 the population would have declined by 25%. To prevent a decline it would be necessary to increase the average size of families by one in three at once, which was clearly impossible. Statistics had just been published by the Registrar-General to show that the birth rate for the March quarter had risen to 16.8, the highest for fifteen years. There was no mention that in 1917, after a precipitous decline of 26% during the first three years of the last war, the birth rate was then 17.8. During the last war, in spite of the great prosperity of the people, the birth rate persisted in falling. Not only in this country but almost throughout the world a declining birth rate had gone hand in hand with improved conditions. The most advanced countries, generally speaking, were those with the lowest rates. The removal of the unequal burden on the married man was the key to the whole problem if they agreed that children were a national asset.

Miss RATHBONE said the lowest birth rate of all was found among ministers of religion, doctors, and teachers. They represented the intelligent persons who were not willing to have large families in present circumstances. Only a few municipalities had introduced a scheme of rent rebates in respect of dependent children where the family income fell below a certain standard. Mr. JAMES GRIFFITHS said a large number of women had one child and refused to have another. It was essential to make motherhood safer. Another reason for the fall in the birth rate was that women increasingly desired a career and the social system compelled women to choose between a career and motherhood. A system must be devised whereby both were possible. Mrs. BEATRICE WRIGHT considered that many women were permitted under war conditions to stay at their work too long and to resume it too soon after their babies were born. Family allowances would meet this.

Fertility and Contraceptives

Captain ELLISTON said a modest start in dealing with the problem of declining fertility was made in 1937 when the Government brought in the Population (Statistics) Bill. That Bill had been treated with levity from the moment of its introduction. They were told that there was no evidence of increasing physical sterility, but that there was a deliberate policy adopted by parents to limit their families to one or two so that children could be brought up in greater comfort and security and with greater educational advantages. Some health experts said that by passing a Bill to prohibit the sale of contraceptives the problem would be settled. Others were not sure the availability of contraceptives was wholly responsible for the fall in fertility. Lord Geddes, during a discussion in the House of Lords, had suggested that the decline in fertility was a biological problem and that the germ plasma had ceased to be actively reproductive. Research had been made into similar symptoms in the case of pedigree cattle, and if pro-

cautions were taken with cattle, could not provision be made for research when the preservation of human beings was concerned? Scientists had not yet reported whether the long-term effect of contraceptives rendered women less liable to pregnancy when that condition was desired. These matters called for inquiry by some such body as the Medical Research Council, the Royal Society, or the universities. Dr. EDITH SUMMERSKILL said contraceptives had been prohibited in France for many years, but the birth rate was still declining rapidly. In this country the woman in industry had to go on working until far advanced in pregnancy because she did not receive National Health Insurance benefit. Service allowances were so small that she was forced to remain in industry. Maternity accommodation was overcrowded. The Government had done nothing in these matters.

Sir FRANCIS FREMANTLE said the declining birth rate had resulted in the loss of leaders. But those who condemned contraceptives lent aid to a tendency, which the medical profession knew too well, toward abortion, although not, as in ancient Rome, toward infanticide. Among the younger generation during this war sexual promiscuity seemed almost the rule in large cities. That was the natural result of contraceptives and of the urge of life if there were no spiritual or moral authority against it. The medical profession was alarmed because the use of contraceptives was believed to be responsible, though they did not know to what extent, for some of the unwanted sterility at present. It seemed clear that the virgin womb was affected by contraceptives with a sterilizing result. There was a great deal of unwanted sterility at present. They might discuss whether contraceptives should be distributed to the unmarried under a certain age, or sold only under a definite certificate from the justices or from the medical profession. Lady ASTOR said it had been known for years that out of 600,000 children born 25,000 were stillborn, that 35,000 died before the age of 1, and that 11,300 died between the ages of 1 and 2. Remedies were available for these evils.

"Exceptional" Rate of Last Century

Mr. ERNEST BROWN, replying to the debate, said it was true that information was incomplete as to the numbers of families with one, two, three, or other numbers of children, or as to differences in family patterns exhibited by different occupational groups. That information could be obtained only by a census, which would have been taken in 1941. With families broken up and dispersed as they were to-day, and with the large proportion of parents in the Forces, the information obtainable from a census would be of little value. That inquiry must be postponed until conditions became more settled, and then it would be made. It was a misreading of the problem to regard the reproduction rates of the nineteenth century as normal. The high reproduction rates then experienced in this and other Western nations resulted in exceptional growth of population, which had been characterized as "one of the great population surges of history." In Great Britain the population more than trebled during a hundred years, and thereafter increased to its present size of between 46,000,000 and 47,000,000, with a density in area which was the highest in contemporary record. If the nineteenth-century rate of growth had continued the population by the year 2001 would rise to 111,000,000. A check had to come sooner or later, and it did come. He would not say that that check had not gone perilously far, but there was no justification for expecting a further decline in the birth rate solely by reason of what happened in the different circumstances of the past.

Promise of Government Inquiry

The rate ceased to fall in 1933, and with the improvement in economic conditions after 1932 had shown a small increase since that time. The response of the birth rate to changes in employment had been marked over the whole period of 1924 to 1939. The curve of the birth rate followed that for unemployment with remarkable fidelity, showing that economics had a big effect. Between 1914 and 1918 birth rates fell precipitously, whereas in this war, though small decreases were recorded in 1940 and 1941, they were more than restored in 1942 by a rise to a position not previously reached since 1931. They had had six successive quarters in which there had been increases, and there was a prospect of further material improvement this year. That recovery had been aided by the high marriage rates, and these by raising the proportion of young married women in the population, must have prolonged influence on fertility. The vital statistics affecting mothers and young children had improved. Last year England and Wales had the lowest rates on record for maternal mortality, stillbirths, and infant mortality and the lowest death rate from diphtheria. That was a tribute to the co-operation of Government, local

government, and voluntary effort. In the fourth year of the war young children were healthier, taken all round, than they were in peacetime.

The Government intended to institute an inquiry on the broadest basis into the whole question of birth rate and population. The form of the inquiry and the terms of reference were matters for early decision. No such inquiry would be valuable without the full participation of women, and particularly of women who had experience of motherhood. A census would be taken at the earliest time when the Government was satisfied that it would gain a true result.

The debate then concluded.

Specialists in the Army Medical Services

On July 14 Sir JAMES GRIGG informed Mr. Rhys Davies that there were psychiatrists serving in the R.A.M.C. many years before the war, but the first new appointment after the outbreak of war was made on Sept. 8, 1939. There were 198 now serving. Since the beginning of the war about 23% of those discharged from the Army on medical grounds had been discharged for psychiatric reasons.

Sir James Grigg also informed Mr. Naylor that the following categories of specialists were employed in the Army Medical Services: physician, neurologist, physical medicine, dermatologist, physiologist, pathologist, psychiatrist, venerologist, hygiene, malarialogist, entomologist, surgeon, radiologist, ophthalmologist, oto-rhino-laryngologist, anaesthetist, neurosurgeon, maxillo-facial surgeon, orthopaedic surgeon, and gynaecologist. They were primarily engaged on their specialist duties. If there happened to be a shortage of general duty officers, they might, however, be required in addition to undertake general medical duty.

Detention Barracks Inquiry

Mr. MR. CHURCHILL, in reply to Mr. Bellenger on July 20, said that Mr. Justice Oliver had consented to be chairman of the Court of Inquiry into detention barracks. The other members would be the Bishop of Reading and Lord Moran. These three distinguished men, though belonging to very different vocations, all gained the Military Cross for gallantry in the last war, and were, therefore, acquainted with military matters. The inquiry would be held in private and not under the Tribunals of Inquiry Act, 1921. The report would be published.

Mr. SHINWELL: While not questioning the intelligence or bravery of the distinguished persons to whom the Prime Minister has referred, can he say whether any of them at any time have ever been incarcerated? Mr. CHURCHILL: That has never yet been made an indispensable condition for membership of a public inquiry!

The following are the terms of reference: To inquire into and report on the treatment of men under sentence in naval and military prisons and detention barracks in the United Kingdom, and whether it is in accordance with modern standards and satisfies wartime requirements. The investigation will cover, *inter alia*, the supervision and administration of discipline, medical care, training, welfare, accommodation, feeding, and the suitability and adequacy of the staff.

Pay of Mental Nurses.—Lord SNELL in the House of Lords on July 8 announced that a subcommittee in association with the Rushcliffe Committee would be appointed to draw up agreed scales of salaries and emoluments of nurses in mental hospitals and mental deficiency institutions in the light of the recommendations made by the Rushcliffe Committee. The chairman of the subcommittee would be appointed by Mr. Ernest Brown.

Reasons for Discharge from Army.—On July 13 Mr. HUTCHINSON asked the Secretary of State for War whether he would give instructions that the entry in the discharge papers issued to a soldier discharged as no longer physically fit for service would be so expressed as to make plain the reasons for discharge. Sir JAMES GRIGG replied that the inclusion on the discharge certificate of the specific nature of the disability would, in many cases, be to the detriment of the ex-soldier who in seeking employment was asked to produce his discharge documents. It was therefore considered that no change should be made in the present practice.

Batteries for Deaf-aid Appliances.—Mr. DALTON, replying to Sir Jocelyn Lucas on July 13, said he fully appreciated the importance of maintaining the supply of batteries for deaf-aid apparatus; and he was aware that, owing to urgent war contracts, there had been some shortage recently of certain types of batteries. He hoped that, as a result of arrangements which he had now made, the manufacturers would soon overtake arrears.

Notes in Brief

During a discussion in the House of Lords on the Catering Wages Bill Lord Snell said that hospitals, so far as kitchen staff were concerned, would come under the Bill like any other undertaking.

Legislation is under consideration to give effect to recommendations of the Interdepartmental Committee on the Rehabilitation and Resettlement of Disabled Persons.

Medical News

On June 1 Major-General Norman T. Kirk succeeded Major-General James C. Magee as Surgeon-General of the United States Army, and a few days later addressed the House of Delegates of the American Medical Association at its opening session in Chicago.

The Association of Speech Therapists will hold a conference on Thursday and Friday, Aug. 5 and 6, in the Hastings Hall at B.M.A. House, Tavistock Square, W.C. On Aug. 5 at 11 a.m. Dr. C. Worster-Drought will speak on "Congenital Auditory Imperception and its Relation to Speech Defects," and at 3.15 p.m. Dr. Helen Doris Watson on "Relaxation."

A special general meeting of the British Institute of Radiology incorporated with the Röntgen Society will be held on August 7 at 2.30 p.m. in the Reid-Knox Hall of the Institute, 32, Welbeck Street, W.

At a meeting recently in the Albert Hall Sir Peter Chalmers Mitchell, treasurer of the Joint Committee for Soviet Aid, handed to M. Maisky, the Ambassador of the U.S.S.R. in Great Britain, a cheque for £40,000 towards the Stalingrad Hospital Fund. More money is still needed for this, and contributions should be sent to the Joint Committee, 171, St. Stephen's House, Westminster, London, S.W.1.

The issue of *Archives of Surgery* for May, 1943, is dedicated to Dr. Robert B. Osgood, professor emeritus of orthopaedic surgery at the Harvard Medical School.

The Sixth Addendum to the *British Pharmacopoeia*, 1932 (see *Journal*, June 26, p. 797), will be published on Aug. 1, 1943, and become official from that date.

At the recent conference of the Liberal Party a resolution on "Land and Housing," asking that the Minister of Town and Country Planning should have adequate powers to make and enforce a national plan for necessary reforms, was amended without dissent to include "the progressive elimination of the smoke nuisance."

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* during the week there was little change in the trends of infectious diseases, although measles notifications fell by 572. The returns for diphtheria were 28, acute pneumonia 28, dysentery 27, and scarlet fever 25 fewer than in the preceding week; the returns for whooping-cough rose by 35.

In the counties the largest falls in the measles figures were in Monmouth by 110, in Essex by 96, in Surrey by 70; and the only notable rise was that of Somerset, 38. The 71 cases recorded in Cambridge constituted the largest weekly total recorded in this country during the present epidemic. Since March, when the epidemic was at its height, the geographical distribution has changed, and the disease is now, proportionately, more concentrated in the South. The proportion of cases in the combined divisions of London, South-East, and South-West is now 35% of the whole country, compared with an average of 25% during March, while the proportion for the Yorkshire, North-West, and Northern divisions has fallen from 27 to 20%.

The only variations of note in the trends of the other infectious diseases were 39 fewer cases of scarlet fever in London and 35 more in Yorks West Riding; the notifications of whooping-cough were up by 52 in Yorks West Riding.

The fall of 27 in the notifications of dysentery has brought the total below the 100 level for the first time for eight weeks. A fresh outbreak occurred in the rural districts of Wiltshire, attacking 8 persons. There were 14 more cases in Bristol C.B. The other large returns were London 12 and Yorks West Riding 10.

In *Scotland* the incidence of measles was down by 137, of diphtheria by 45, and of whooping-cough by 39 cases; but that of scarlet fever rose by 8. The number of cases of dysentery remained unchanged at 64, the chief centres of infection being Edinburgh 12, Aberdeen 11, Dundee 10.

In *Eire* the rise in the notifications of measles was due to an outbreak in Co. Kerry, Gort R.D. 18.

The Week Ending July 17

The notifications of infectious diseases in *England and Wales* during the week included: scarlet fever 2,082, whooping-cough 2,150, diphtheria 571, measles 3,054, acute pneumonia 457, cerebrospinal fever 51, dysentery 160, paratyphoid 11, typhoid 11.

INFECTIOUS DISEASES AND VITAL STATISTICS

No. 27

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended July 10.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1943					1942 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)

† Includes puerperal fever for England and Wales and Eire.

‡ Owing to evacuation schemes and other movements of population, birth and death rates for Northern Ireland are no longer available.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1.

ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Secretary of the Journal Board, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be sent to the Secretary.

TELEPHONE NO. B.M.A. and B.M.J.: EUSTON 2111.

TELEGRAPHIC ADDRESSES—EDITOR, *Antology Westcent*, London; SECRETARY, *Mediscera Westcent*, London.

B.M.A. SCOTTISH OFFICE: 7, Drumshough Gardens, Edinburgh.

ANY QUESTIONS?

Risks of the Rh Blood Factor

Q.—What steps can be taken to avoid the death of the foetus where the father has the Rh-positive factor in the blood and the mother has not? How is the diagnosis made? Is it necessary to test samples of blood from both mother and father? What is the treatment? Does the treatment begin before the birth of the child? Is it wise to test every pregnant woman (i.e., primipara) for presence of Rh factor in the blood?

A.—At present no method is known of preventing anti-Rh agglutinin in an Rh-negative mother's serum from killing her Rh-positive foetus. It may be that, in future we can isolate a polysaccharide responsible for the specificity of the Rh antigen, its injection into the mother may neutralize her anti-Rh and prevent or diminish its harmful effect on the foetus. Although no treatment is possible before delivery, steps can be taken during pregnancy to insure that proper treatment is available if it is needed when the child is born.

Ideally the Rh position would be investigated in every pregnancy. That a woman is Rh-positive does not mean that she and her children are certain to be free from trouble caused by Rh. Erythroblastosis foetalis has been caused by an Rh-positive mother making an unusual type of anti-Rh which clumps the red cells of all Rh-negative and those of many Rh-positive persons, including the child's. This unusual antibody, anti-Rh, may be formed when the husband and the foetus, as well as the mother, are Rh-positive. Nevertheless, 90% of erythroblastic babies have Rh-negative mothers, and when a woman is known to be Rh-negative it is wise to remember this. Rh may cause erythroblastosis in a first baby, but only very rarely, and there is some evidence that when a first-born is affected the mother is most often Rh-positive. In the immediate future, at any rate, it seems that investigations will be confined mostly to cases where erythroblastosis has occurred or is suspected, or where there has been a series of miscarriages or stillbirths. Only one person in seven is Rh-negative; in one mating in eight the mother is Rh-negative and the father Rh-positive; and in one pregnancy in ten the mother is Rh-negative and the foetus Rh-positive. So it is clear that the Rh factor causes trouble in only a small proportion of the pregnancies in which the Rh groups make trouble possible.

To investigate a case samples of blood from mother, and, if possible, from father and all their children, should be tested for the ABO and Rh factors, and the mother's serum examined for the presence of anti-Rh or other irregular agglutinins. The Rh antigen is detected by the red cells containing it being agglutinated when mixed with anti-Rh sera. Mothers of erythroblastic babies or people who have had transfusion reactions due to Rh form the most convenient source of antisera. Anti-Rh or other unusual agglutinin in the mother's serum is sought by seeing whether the serum will clump red cells from a panel of donors chosen to cover the range of known antigens. Rh tests should be made in tubes and not on a tile or slide; some experience is needed to make and interpret them properly. With a suggestive history, finding that the mother is Rh-negative makes it very likely that erythroblastosis will affect the children; knowing that the father is Rh-positive increases the chances, and if anti-Rh is found in the mother's serum trouble is almost certain. When such findings are made during pregnancy it should be arranged that O Rh-negative blood is available in case either the newly born baby or the mother should need transfusions.

As soon as a diagnosis of erythroblastosis foetalis has been made—and where there is a previous history the cord blood should be examined at once—the child should be transfused with O Rh-negative blood. The blood should be injected into the veins, not into the muscles. The mother's whole blood, although Rh-negative, should not be used, for its plasma will almost certainly contain the harmful antibody. If no other negative blood is available, and if the ABO groups permit, the mother's cells washed free from plasma may be injected. If Rh-negative blood is not available from

any source the child may have blood from a group O donor taken at random, but such blood will usually be Rh-positive and may cause a transient jaundice. It is better to seek a donor among the mother's relatives than to use the father or his relatives—the chance of the donor being Rh-negative is greater.

Treatment of Tapeworm Infection

Q.—I should be very glad of advice on the treatment of a patient with a tapeworm (*Diphyllobothrium latum*). My routine has been to starve her to begin with, then to give alkaline drinks to remove mucus, and finally to administer extract of male fern. This treatment has on several occasions brought away large segments, but the head obstinately remains behind. If the tapeworm wins, I lose a patient.

A.—For two days before specific treatment food should be restricted to coffee, tea, toast-and-butter, breakfast cereals, eggs, and glucose. During these two days 1/2 teaspoonful of sodium bicarbonate stirred into a tumbler of water should be taken four times daily. On the day of treatment sodium sulphate, 200 gr., should be taken in hot water at, say, 7 a.m. This may be followed by a drink of hot tea without milk. At 8.30 a.m., 9 a.m., and 9.30 a.m. 30 minims of extract. filicis liq. should be taken. The patient must lie in bed during this time, and at 11 a.m. a further dose of sodium sulphate should be taken. If this fails to produce the desired effect, recourse may be had to carbon tetrachloride. The same preliminary starvation and purging should be carried out, and 3 c.cm. of the drug and 1 c.cm. of oil of chenopodium emulsified in liq. paraffin (30 c.cm.) should be taken. Carbon tetrachloride is not devoid of danger on account of toxic action on the liver. A saline aperient should be taken within one hour.

Ending Lactation

Q.—When for any reason it is not advisable for a woman to feed a child on the breast, will administration of oestrogens suffice to prevent lactation? What, for example, should be the dosage of stilboestrol in such cases, and for how long should it be given? Similarly, are oestrogens useful in terminating lactation at the usual time, and are supplementary measures advisable or to be preferred?

A.—Lactation can be prevented or suppressed with oestrogens in nearly every case providing the dosage employed is adequate. No supplementary measures are necessary. Begin treatment as soon as possible after delivery and give 5 mg. stilboestrol twice by mouth for the first day. Thereafter reduce the dose at the rate of 1 mg. a day, completing the course of treatment in ten days. Gradual reduction of the dose is important. Oestrogens are equally efficacious in suppressing breast activity at any time after delivery and even when lactation has been in progress for several months.

Sudden Loss of Hair

Q.—A newly retired schoolmaster, aged 64, two years ago and in the space of about 2 or 3 weeks suddenly became completely hairless. There has been no indication that the hair might be growing again since that time, and he still has no need of a razor. Apart from this he is apparently completely fit. Both he and I will be grateful for (a) suggestions for treatment, and (b) indications of the prognosis either with or without treatment.

A.—Total alopecia is usually the result of shock or severe acute anxiety. Apart from the very rare occurrence of Simmonds's syndrome following shock, there is no real evidence that this alopecia occurs via the hypothalamic-pituitary neuro-endocrine mechanism, although one is tempted to advance some such hypothesis. Against it, however, is the absence generally of any other endocrine manifestation. Further, hypogonadism, especially complete castration before puberty, is associated with little or no hair on the face and pubis, but much hair on the head, and a tendency to retain it throughout life. On the other hand, virile men with full sexual potency may go completely bald, and virilized women lose the hair of the head. From the endocrine point of view, therefore, there is a dissociation between the hair of the head and the hair of the face and pubis. From the point of view of treatment, testosterone might be helpful in restoring the hair of the face (and sexual potency if such were lost), but would have no effect on the hair of the head. Thyroid has been given traditionally, but it is doubtful if it is effective. Psychotherapy is indicated.

Hodgkin's Disease

Q.—A boy of 12 suffering from lymphadenoma has been relieved by operation followed by x-ray treatment. X-ray treatment is now suspended and the possibility of vaccine treatment is being considered, as this has been under trial for some time. Can you supply information as to the nature of the vaccine and where it may be obtained?

A.—Coley's fluid was probably the first bacterial inoculation used in the treatment of Hodgkin's disease and it is still occasionally employed. A few successes have been reported. The fluid contains

the combined toxins of *Streptococcus erysipellatis* and *B. prodigiosus*, and it should be obtainable from any large pathological laboratory. It is injected daily, in the neighbourhood of the glands if there is still any lymphadenopathy, in a dose of 0.25 to 0.5 minim, and if little or no reaction is obtained the dose is increased by 0.25 or 0.5 minim daily until a rise in temperature of 102° to 104° is reached. The injections are then continued till the reactions calm down and the temperature falls. Over ten years ago the view was advanced that Hodgkin's disease was a form of avian tuberculosis, and an antiserum was prepared by inoculating chickens with lymphadenomatous tissue. This serum was completely ineffective in treatment. More recently Gordon demonstrated the presence of an encephalitogenic agent in the glands in Hodgkin's disease and treated a few cases with a "sensitized vaccine" obtained from material from the glands. It is not generally believed that the encephalitogenic material is a pathogen, for similar material can be obtained from normal human marrow and occasionally from leucocytes. Preliminary reports of the treatment were not encouraging. Details of preparation of the vaccine were given by Gordon (*Proc. roy. Soc. Med.*, 1936, 30, 541), but it is not available commercially.

Visceral Lesions after Muscular Action

Q.—Is there any evidence that the contraction of the abdominal muscles which takes place in the lifting of heavy weights can cause any visceral lesion (such as gastric ulcer) in the male subject, apart from hernia?

A.—The relationship of visceral lesion to injury of the abdominal wall is one which is frequently under discussion in the law courts, usually without much "conviction" on either side. That violent injury to the abdominal wall can damage the underlying viscera is beyond doubt, but this question concerns the effects of muscular contraction. The great mobility of the majority of the viscera within the peritoneal cavity is a provision against injury as a result of muscular action, but with this protective mechanism adhesions might obviously interfere. It may therefore be fairly stated that it is highly improbable that such a disease as gastric ulceration could arise from parietal muscular contraction. But while it is impossible to state categorically that no visceral disease could in any circumstances be produced by muscular action, it is equally impossible to produce incontrovertible proof that such conditions can be so produced. In most cases in which it is alleged that the disease was the result of muscular action the truth is that the first evidence (pain or tenderness) of the onset of the condition was produced by some muscular contraction, but that the disease itself pre-existed. This is often demonstrated in appendicitis.

London Paste

Q.—Is it safe to use "London paste" for reduction or destruction of diseased tonsils?

A.—There is no particular danger in the use of London paste, which is a strong caustic, if care is taken to ensure that it is applied only to the surface of the tonsil and is neutralized by some weak acid after application. It produces a superficial slough, followed by fibrosis and scar formation which seals the crypts and causes retention of secretion in the remainder of the tonsil. Dissection of the tonsil afterwards is therefore much more difficult. Morell Mackenzie (*Diseases of the Nose and Throat*, vol. 1, p. 36, J. and A. Churchill, London, 1880) recommended applications on his spatula for granular pharyngitis. It does not appear that he either attempted to destroy the tonsils with it or recommended this. The answer to the question must be that there is no immediate danger to the patient, but that London paste cannot possibly succeed in a complete removal of the tonsil, leaves remote ill effects, and is not safe for the reputation of a practitioner who employs such a discredited method of treatment.

INCOME TAX

Deduction of Professional Subscriptions

E. B. holds an appointment at an E.M.S. hospital under the Ministry of Pensions. He has claimed to deduct sums paid as subscriptions to the B.M.A. and various other professional associations, but is informed that they are not allowable as he is assessed under Schedule E.

* It is understood that a Government Department does not require its officers to belong to the associations in question, and if so the subscriptions are not allowable for income-tax purposes. The question was before the Court in a similar case (*Simpson v. Tate*) in 1925, and a decision was given in favour of the Revenue's view that such an allowance is prohibited by the strict rule applying to Schedule E assessments. In his judgment Mr. Justice Rowlatt observed: "I think that all subscriptions to professional societies, and all taking in of professional literature, and all that sort of expense which enables a man to keep himself fit for what he is doing, are things which can none of them be allowed."

LETTERS, NOTES, ETC.

Plugging Tooth Sockets

Mr. F. ELLIOTT SMITH, M.R.C.S., L.D.S. (London, W.1) writes: With reference to the reply (July 3, p. 30) under "Any Questions?" to a query as to the treatment of haemorrhage after tooth extraction, may I refer to the reply of Mr. Angelman (Oct. 24, 1942, p. 504) to a series of letters on the plugging of tooth sockets, and ask, as he did, why it is done. Unfortunately, at the time it is effective. The after-effect, at the best, is an open socket to collect food debris; at the worst, an entry for infection with a risk of a "dry socket," which is painful and very obstinate to treat. In the majority of cases digital pressure on the sides of the socket and gentle firm pressure on a pad of gauze, with or without a composition splint, followed, if necessary, by a stitch or two, will stop the bleeding. The patient should be told to keep quiet, avoid stimulants, and not lie flat. With reference to the composition splint, prolonged vertical pressure on a pad is very apt to "mushroom" the socket and tissues again, and therefore the side pressure given by the splint is a help. Styptics and haemostatics are of doubtful value, with the possible exception of calcium prophylactically (a controversial point) and morphine, as part of the treatment. I would suggest, to the dental surgeon—avoid laceration; and to the doctor—that plugging should be forgotten and that pressure and stitching will be effective and better treatment. Haemorrhage due to blood and general conditions will call for different treatment—for example, transfusion given early. The dentist should himself treat the damage done, as the doctor will justly retort.

Two Cases of Epilepsy

Dr. A. W. DAVISON (Stretford, Manchester) writes: The occurrence of incontinence in the two cases of epilepsy referred to in "Any Questions?" (July 17, p. 93), during the attacks, suggests a diagnosis of narcolepsy. Try benzedrine sulph. 10 to 20 mg. or ephedrin. hyd. gr. 1/2 m. et n.

Public Vaccination

Dr. M. F. McDONNELL (Northfleet, Kent) writes: Perhaps in these days of petrol shortage the following suggestion may be of some use to public vaccinators, especially those with large rural districts composed mainly of isolated hamlets. I have found by experience that quite a large proportion of the mothers go out to some form of daily work, and that time and petrol are wasted on fruitless calls at their homes, when one is informed (provided one is lucky enough to find anybody at home) that mother has taken baby to work or "So-and-so's farm," etc. As soon as I am aware of the existence of a baby I send a stamped addressed postcard with the following on the reverse side:

- * Please call to vaccinate baby on
- * I do not wish to have baby vaccinated
- * Baby has been vaccinated by Dr.
- * Please cross out as necessary. Return card immediately.

I might add that more than 60% of the babies in this area are vaccinated.

First Aid for Fractured Spine

Mr. DESMOND MULVANY (Hospital of St. John and St. Elizabeth N.W.8) writes: With reference to Dr. Moir's letter (May 15, p. 614 regarding first-aid treatment for fracture of the spine, I consider that if there is to be any drastic change in the teaching on this subject the suggestion should come direct from the British Orthopaedic Association to the various organizations concerned, and not from any one individual. Alternatively these bodies could submit to the Association the present-day first-aid treatment, with which it is not necessarily familiar, and request that an alternative line of treatment should be drawn up if it was deemed advisable. Personally I consider the present St. John's teaching to be quite satisfactory. It deals with a difficult subject in a most concise and lucid manner; I feel that any further alternative methods would only confuse the issue.

Invasion of Earnigs

Dr. G. STEPHENS (Windsor) writes: In your *Journal* of July 11 p. 62, there is a reply to a question about an invasion of earwig. For many years I had been worried with invasions of these pests. The only relief I found—and it was a perfect cure against the insects in the house—was to paint a continuous line, about one inch in width, completely round the house, with "sticktite" or some other fruit-tree band preparation. If this line comes just below the door step it will not inconvenience anyone. But wireless earth wire and the stems of creepers or trees that may be touching the wall anywhere, must have their own ring of "sticktite."

Exchange of Raincoats

Mr. D. C. DICKSON, F.R.C.S.Ed., 10, Woodlands Road, Middlebrough, writes: Will the surgeon who took the wrong Warwicks Dunlop raincoat at the Royal College of Surgeons meeting (Wednesday, July 21, communicate with me, as I have his coat.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY AUGUST 7 1943

SOME PROBLEMS IN THE CONTROL OF INFECTIOUS DISEASES*

BY

ROBERT CRUICKSHANK, M.D., M.R.C.P., D.P.H.

The mortality from infectious diseases has declined steadily and steeply in the past half-century; yet to-day approximately one death in five is attributable, directly or remotely, to infection. The problem of the control of infectious diseases is a complex one, for "it includes all measures which decrease damage, whether physical, economic, social, or psychological, to the human host as a result of disease, and with no marker to indicate where actual preventive medicine leaves off and good clinical medicine begins." To assess the value of past measures and as a guide to further progress the bulk of infectious diseases in this country may be considered in four main groups: (1) *Acute respiratory infections*—the pneumonias, influenza, and the common cold; (2) *Tuberculosis*; (3) *Intestinal infections*; and (4) *Childhood fevers*—pertussis, measles, diphtheria, and scarlet fever, in that order of importance. But if all other streptococcal infections are added to scarlet fever that group becomes one of the principal causes of invalidity.

This list excludes at least two important groups—infections of the central nervous system, and venereal disease. Cerebro-spinal meningitis and poliomyelitis have each so complex an epidemiological picture that I have no space to discuss them here, while the control of venereal disease is such a controversial problem just now that I propose to leave it alone.

Acute Respiratory Infections

The Pneumonias.—There has been an irregular but appreciable decline in deaths from pneumonia since the beginning of the century, more so in the adult age groups than in the young and not at all among the aged; yet some 40,000 deaths are still attributable yearly to pneumonia and bronchitis. The introduction of sulphapyridine in 1938 brought high hopes that pneumonia would cease to be one of the captains of the men of death; but, in fact, deaths from this infection during 1939-41 were for England and Wales still 88% of the average figure for the previous four pre-sulphonamide years—1934-7 (Martin, 1942).

It may be assumed that most primary pneumonia in this country is due to infection with the pneumococcus, and pneumococcal pneumonia occurs in two clinical forms—lobar pneumonia, which is an infectious disease of older children and adults, and bronchopneumonia, which is largely an auto-genous infection of the very young and the very old. Hospital figures show a reduction in the case fatality of sulphonamide-treated lobar pneumonia to about one-third of pre-sulphonamide days; whereas in all Scotland, where deaths from lobar and other forms of pneumonia are differentiated, mortality from lobar pneumonia in the years 1939-41 was still three-fifths that of the 1934-7 period. These figures suggest that cases are being treated more effectively in hospital than in the home. If that be true—and too often the practitioner gives too small a dose for too short a period—then more hospital pneumonia units might well be established in industrial towns where the infection is prevalent. The factors which affect prognosis in lobar pneumonia, such as age of patient, infecting pneumococcus type, extent of lung involved, and bacteraemia, are

more readily determined in hospital, where appropriate dosage can be more easily arranged.

Such scanty data as exist on the sulphonamide therapy of bronchopneumonia indicate that a considerable reduction in mortality has been effected among hospital cases of primary bronchopneumonia in children; yet the figures from Scotland show that in the sulphonamide years there has been only a 15% reduction in mortality from "other forms of pneumonia," compared with a 40% reduction in lobar pneumonia. The explanation of this remarkable disparity is perhaps to be found in the differences between the two infections. Lobar pneumonia is an exogenous infection of lung tissue by a highly invasive pneumococcus in a healthy child or adult who either lacks some specific antibody or whose resistance is temporarily impaired, as by fatigue or an antecedent cold. The sulphonamides seem to be most effective against actively invasive pathogens, and this factor, together with the ready response of healthy tissues to infection, helps the individual to overcome the invading pneumococcus. Bronchopneumonia is usually an autogenous infection in a poorly resistant individual by pneumococci of low virulence. The infection affects primarily the mucous membrane of the bronchial tree, where the organism is badly placed to stimulate production of antibody and is less accessible to the drug. Moreover, the tissues of the very young and the very old are perhaps less able to kill a pathogen which the sulphonamide can only prepare for destruction. Thus the factor of non-specific resistance probably plays an important part in the successful administration of a chemotherapeutic substance.

The bronchopneumonia of the aged may often be an unavoidable terminal infection, but there is something far wrong with a nation's health which allows bronchopneumonia to kill every year 7,000 to 8,000 children under the age of 5 (see Table). Mortality from pneumonia at this age is four to

Table showing Deaths in Children, 0-5 years; England and Wales, 1938

seven times greater in industrial and working-class districts than in residential areas. Thus poverty is a principal predisposing cause; but which factor in poverty—poor nutrition, poor hygiene, poor environment, or way of life—is most important we do not know. Certainly rehousing does not *per se* improve matters much, and anyone who has read *Our Towns* (1943) will realize how difficult it will be to eradicate slum habits, with their evil influence on the health of young children. The higher infant mortality rates of the Northern industrial areas are largely due to an excess of deaths from respiratory infections, and here the harsher climate is an important contributory factor; yet Huddersfield has shown that these adverse conditions can be overcome. Provision for earlier and more frequent hospital treatment of young children

* A Chadwick Lecture, given on March 16, 1943.

with measles and pertussis in the industrial North would probably help to lessen this appalling mortality from bronchopneumonia.

Influenza.—Many of us are wondering if there is any likelihood of a pandemic of influenza in this Second World War similar to that which happened in 1918. The 1918 pandemic—the first of its kind to coincide with a major war—probably owed its origin to other factors than war-weariness, malnutrition, and the herding together of men; but its spread and its ravages were doubtless facilitated by these abnormal conditions. Any spark, in the shape of men drafted from an epidemic focus to war-stricken Europe, may set the flame alight again. In considering whether anything can be done to forestall or limit a possible pandemic, the following facts are relevant. Influenza is due to a number of viruses, of which two varieties have already been isolated and labelled influenza virus A and B. After a clinical attack, specific antibody, which can be readily detected by a simple test, develops to these viruses; many individuals during an epidemic develop antibody without being clinically affected. Thus by taking blood from representative samples of the population we can tell whether the community possesses a low or a high degree of resistance to the influenza virus. Ordinarily the virus attacks only those individuals with little or no immunity, and it is perhaps disturbing that there has been scarcely any epidemic influenza due to virus A or B in this country since 1937. Vaccines have been prepared from influenza virus A, and in controlled institutional trials they have, when used prophylactically, reduced the incidence of infection by about one-half. But in the presence of a highly virulent strain of pandemic propensities a moderate degree of immunity would probably be insufficient to protect against infection. Burnet and Clark (1942) in their excellent monograph advocate for such a contingency immunization by spraying the upper air-passages with a living but attenuated virus which could be quickly prepared in large amounts in chick-embryo. There is much to do along these lines, and every opportunity and encouragement must be given to laboratory workers to develop some such mode of defence. Until specific prophylaxis becomes practicable, strict quarantine is the only reliable means of protection, and in the event of pandemic influenza on the Continent an attempt to quarantine this island might be worth while; for, if even only partially successful, it might slow down the spread and thereby attenuate the virulence of the virus.

In the presence of a pandemic the wearing of efficient masks by those in close contact with infected cases will afford protection, while bactericidal mists or vapours (sodium hypochlorite, esorcinol, propylene glycol) could be used as aerial disinfectants in public meeting-places. Throat sprays and gargles are useless. With mucous membranes made highly susceptible, secondary infection is the great danger in influenza, so that initial cases should be isolated early, preferably in their own homes. Herding together of patients, as was done in 1918, courts disaster from secondary bronchopneumonia due to cross-infection with the streptococcus, staphylococcus, etc. If institutional treatment is unavoidable, wards must be kept well ventilated, beds widely spaced, and floors and bed-linen treated with oil (Van den Ende and Thomas, 1941). Best results in 1918 were claimed by those who nursed patients in the open with only a canvas canopy over their heads. There was little secondary pneumonia in the summer epidemic wave of 1918.

The Common Cold.—American analyses have shown that each of us has an average of three colds a year. Much invalidity from otitis media (10% in children under 5), sinusitis (6.6% in older patients), bronchitis (one-third of the cases), and pneumonia is directly attributable to the common cold. If colds have a varied aetiology, there is strong supportive evidence for an elusive filterable virus as a causative agent (see Browning, 1942): experimentally only chimpanzees have been successfully infected, and only one team of workers has aimed to have grown this virus outside the body, so that specific prophylaxis is as yet impracticable. Bacterial vaccines will not reduce the incidence but may lessen the risk of secondary infection. There is some evidence that physical well-being and a comfortable environment increase resistance to the cold. Avoidance of contact with infected persons is virtually impossible, but much can be done by education and propaganda

to make the ungarded sneeze as much of an antisocial habit as spitting now is. In factories and places of entertainment aerial disinfectants may prove to be most useful in preventing dissemination of the virus. And the public could reduce the risk to themselves and to their neighbours by staying indoors for one or two days when they fall victim to this common plague. It constitutes a great economic problem, which might commend itself to the new Nuffield Foundation.

Tuberculosis

The interruptions in the steady decline in mortality from tuberculosis during the First World War and again in the present one have brought home to us the need for greater and unrelenting attack on this infection, which because of its chronicity presents problems of control very different from those of the acute respiratory diseases. The Government wartime promise of more financial assistance to the families of affected persons is an enlightened step in the right direction. Over 90% of the deaths from tuberculosis result from contact with a case of "open" pulmonary infection, and for important points to remember if the downward trend is to be hastened are:

(i) Although most of the population are infected few become infective. Unlike most other pathogens, the tubercle bacillus has the peculiar property of burying itself in the body tissues, and on that minority of infected patients whose lesions break down spreads the disease to others. Yet it has been estimated that about 250,000 cases of open tuberculosis exist in the community (Wingsfield, 1942) and a large proportion of these are undiagnosed. Even among diagnosed cases there is an unduly long lag period between the onset of clinical symptoms and sanatorium treatment. In a recent series the average delay was 9 months, distributed as follows: 3½ months between onset of symptoms and reporting to the doctor; 3½ months before the doctor referred the patient to a tuberculosis dispensary and 2½ months before the patient was admitted to a sanatorium. Only 22% of the cases was sputum sent by the practitioner to laboratory for examination (Mann, 1943). Obviously the methods for earlier diagnosis and treatment of open tuberculosis need to be speeded up.

(ii) Tuberculosis is five times as common among intimate contacts of sputum-positive cases as among the general population, and tuberculous fathers are more common sources of infection for their children than tuberculous mothers. Thus the tuberculosis officer must concentrate on the family rather than on the individual, the detection of early infection among contacts becomes an important function of any tuberculosis service.

(iii) The most susceptible ages are infancy and adolescence. Among infants the infection is apt to become generalized and is fatal; a large proportion of the adolescent cases will, if diagnosed and treated early, join the ranks of the infective. Much stricter regard to personal hygiene would reduce the risk of infection to young children, as shown by the fact that no child in the Papworth Colony has developed tuberculosis. Meanwhile active efforts must be made to protect the susceptible children of tuberculous parents, and artificial immunization with vaccines B.C.G. or Wells's vole bacillus may supply the need. Data from American and Scandinavian sources show that B.C.G. vaccine is a safe and relatively effective means of protecting children, nurses, students in intimate contact with tuberculosis. For example Baudouin in an investigation of more than 2,000 children of sputum-positive parents over a period of 11 years found a tuberculosis morbidity of 31 per 1,000 among the vaccinated and 120 per 1,000 among the controls; the corresponding mortalities were 19 and 1,000, against 54 per 1,000 (see Hopkins, 1941). The problem of artificial immunization needs fresh consideration in this country where in the past 10 years our attitude has been too conservative and apathetic. Mass radiography must be used to detect and control early infection in the adolescent. This is a long-term policy, to be properly done the examinations should begin among children leaving school and be repeated at regular intervals.

(iv) Tuberculosis is closely associated with poverty, and nutrition is probably one of the most important factors predisposing to clinical infection. It is therefore essential that milk, one of the best of foods for children, should be cheap, popular, and pleasant as well as safe to drink. The cheap-milk schemes for mother and child and milk for school children must be continued and extended after the war. Milk-bars help to popularize milk beverage, and we may hope with Mellanby (1939) that "to get children instead of milk may come to be regarded as bad just as it is now considered bad for people to have unwholesome food."

The downward trend of tuberculosis probably owes more to decline in poverty and to improved hygienic conditions in the

munity than to the institution of tuberculosis services; for the mortality rates in other respiratory infections have gone down *pari passu* with that of tuberculosis, and tuberculosis has declined at the same rate in countries with and without public health tuberculosis schemes. It is therefore proper to inquire whether the best use is now being made of the tuberculosis service and to stress again that the tuberculosis officer must be social worker as much as expert diagnostician.

Intestinal Infections

Paratyphoid and Bacterial Food-poisoning.—Typhoid fever is not only becoming rare in this country (mortality has fallen in 60 years from 371 to 6 per million) but should now be easier to control, for the Vi-antibody test and new phage typing facilitate detection of sources, usually chronic carriers, of infection (Felix, 1943; Bradley, 1943). On the other hand, paratyphoid has been unduly prevalent in recent years and bacterial food-poisoning has probably also increased. These two infections are perhaps more closely related epidemiologically than paratyphoid is to typhoid (Savage, 1942). Typhoid fever in epidemic form is often water-borne. Paratyphoid is rarely water-borne, and has a summer rather than an autumn prevalence, usually following contamination of milk, cream, or prepared food by a clinically mild case or carrier. Persistent carriers of the *Salmonella* food-poisoning organisms are rare, but healthy and convalescent carriers are much commoner than was previously thought, and it may be that the human host spreads infection as much as the more commonly suspected rodent. The control of these infections is largely dependent on a high standard of personal hygiene among food handlers, together with improved methods for the protection of milk and prepared foods against infection from human or animal sources. The 1938 Food and Drugs Act decrees that persons employed in a room used for the sale of food are required to observe due cleanliness as regards themselves, the room, and all articles in it; while suitable washing-basins with a sufficient supply of soap, clean towels, and clean water must be provided for their use. It will require much patient education by the medical officer of health and his sanitary inspector to get these regulations observed in the spirit as well as the letter. It might help if all persons handling food for sale were warned by prominent notices of the essential necessity for hand-washing after use of the w.c. and for reporting to their employer any attack of diarrhoea, however mild. The protection by impermeable wrappings of prepared foods against soiling by hands, flies, and vermin also needs to be greatly extended.

Bacillary Dysentery.—There has in the past 10 years been an increase in the reported incidence of bacillary dysentery, mainly perhaps because of the wider recognition of its presence in this country. Even so, many mild and atypical infections are neither recognized nor reported. Case-fatality is ordinarily low, and the worst feature of dysentery in temperate climates is its great infectivity. The introduction of new culture media (Hynes, 1942) has greatly improved laboratory diagnosis and has shown how common are convalescent and symptomless contact carriers, who are a particular danger in wartime: the great increase of dysentery among our troops in France from 1916 onwards was probably related to the transfer of men from the Middle East. In civil life the day nursery, the residential school, the infirmary for the aged, and the mental hospital are the most common foci of infection, but the disease is now endemic in many communities. Fortunately, the new intestinal antiseptics sulphaguanidine and sulphasuxidine can be expected to effect both clinical and bacteriological cure, and the practitioner must realize that bacteriological cure is as important for the welfare of the community as clinical cure is for the individual. The disease is largely spread from case to case by infection of food, and good personal hygiene is again the most important means of preventing it.

Gastro-enteritis.—Infantile diarrhoea to-day levies only one-tenth of the toll exacted 50 years ago; but even now, although the dreaded summer epidemics have gone, it ranks second to pneumonia as a cause of infant mortality, with over 3,000 deaths per annum. Epidemiologically it may be summed up as an infection of artificially fed infants living in urban poor-class districts. The bulk of the deaths occur in the first year of life, and there is little doubt that the disease would practically disappear if all mothers breast-fed their babies for

six to nine months. The fact that only 30 to 50% of mothers feed their infants for even three months is due to a variety of causes. A longer period of rest after confinement, more home help, proper feeding of the mother, the care of the nipples before confinement, more frequent and complete emptying of the breasts during feeding to stimulate lactation and prevent infection through milk-stasis, and, in particular, education of both doctors and the lay public about the advantages of breast-feeding, would all help to secure proper lactation and thus save a large proportion of the 3,000 to 4,000 infants who die every year because they are not breast-fed. That is the long-term policy. Meanwhile the problems of the aetiology and treatment of gastro-enteritis require wide recognition and concerted attention from research teams of paediatrician, bacteriologist, and biochemist working in close co-operation. One point may be stressed: if infants with a liability to gastro-enteritis must be admitted to hospital the should be nursed by isolation technique in single rooms.

Childhood Fevers

Deaths from the four most important childhood fevers—pertussis, measles, diphtheria, and scarlet fever—have declined enormously in the past century. In particular, scarlet fever has ceased to be a killing disease, and now causes less than 5% of the deaths from these four fevers, compared with 40% some 80 years ago. The general decline in mortality has not been accompanied by a fall in incidence, and has occurred at different periods and at different rates for these four infection (see Gale, 1942-3). Deaths from scarlet fever fell precipitously between 1860 and 1900; there was an abrupt fall in the death rate from measles after 1915; diphtheria and pertussis have shown a more steady decline since 1900.

Pertussis.—I put pertussis at the top of the list for three reasons: (1) It is second only to diphtheria as a cause of death among children, and attacks about 70% of the child population, compared with 5% for diphtheria. (2) The protracted nature of the infection and its age of attack are such as to cause much debility predisposing to secondary infection. (3) It is a disease which by prophylactic inoculation can be either prevented or so modified as to cease to be a cause of death or a source of anxiety to parents. I prefer the name "pertussis" to "whooping-cough"; for the whoop comes late in the infection, and doctors and parents must be encouraged to suspect the disease long before it develops. Frequent spasm of coughing, congestive in type, occurring at any time of the day or night and unaccompanied by any physical signs in the chest, should suggest pertussis, and call for further examination. A white-cell count and a blood film at this stage will reveal a leucocytosis with a relative lymphocytosis of 60 to 80%. Confirmation can be obtained by use of the cough-plate, which however, is troublesome and time-consuming for the practitioner. A more practicable substitute is required, and a post-nasal swab inoculated on to a plate of Bordet medium along with an appropriate dilution of penicillin to inhibit other bacteria may supply the need (unpublished observation). With such a method doctor or nurse can take the swab in the home clinic, or nursery, and send it for examination in much the same way as is done for diphtheria. Early diagnosis means early segregation, which not only benefits the affected child but reduces the risk of infection to others. Pertussis is difficult and trying illness, for the mother to nurse at home and a larger proportion of cases than at present should be removed to hospital. But in hospital toddlers should not be confined to bed, for plenty of fresh air and exercise to ventilate the lungs are essential for the treatment of pertussis. Collapses and atelectasis are as common complications as bronchopneumonia, and so long as the children are properly clothed and fed they should be outside most of the day and should sleep on open balconies at night. It is important, too, to impress on doctors and parents that a whooping child has usually passed the infective stage. Hospital beds to the required number cannot be provided if the child is isolated until the whoop disappears.

Prevention is better than cure, and prophylactic vaccination against pertussis is now a practicable and reasonably effective procedure (see Cruickshank, 1942a). Most of the field trials of specific prophylaxis have been carried out in America, where

large weekly injections for three, four, or five weeks, totalling 80,000 million to 100,000 million organisms, have been given. This involves administrative difficulties, and lately a well-controlled experiment by Bell (1941) has shown that two 10,000-million doses of an alum-precipitated vaccine at a month's interval will secure as good results as the more frequent weekly injections. Important points in the prophylaxis of pertussis are the use of a smooth-phase organism, large and slowly absorbed doses, and an interval of four weeks or more between the injections. It might seem an obvious forward step to use pertussis vaccine and diphtheria toxoid together for combined immunization against these two infections; but we must remember that the age of attack for pertussis is much earlier than that for diphtheria, and in fact about half the deaths from pertussis occur in the first year of life (see Table), so that immunization should, if possible, begin at the age of 3 months. Mothers welcome the idea of protecting their children against this disease, which they know from personal experience to be a protracted, worrying, and debilitating infection.

Measles.—The mortality from measles, even allowing for the diminishing population of children under 15, is to-day about one-quarter of what it was as recently as 20 years ago. About two-thirds of the deaths occur between the ages of 6 months and 2 years, mostly from secondary bronchopneumonia, so that the main problem in measles is to postpone the age of attack or modify the infection in young susceptible children. Complete protection is possible by the use of pooled convalescent serum given in 5-c.cm. doses within five days of exposure, but, except in hospital, the date of exposure is seldom known and convalescent serum is difficult to obtain, so that this method is not generally applicable. Besides, it confers only temporary protection for two to three weeks. A modified attack by giving a smaller dose of serum is preferable, but the same difficulties confront us. Thus to protect the young child from measles the choice lies between active immunization and avoidance of exposure. Stokes and Rake (1940) have grown measles virus on chick-embryo, and apparently protected monkeys and human volunteers by intranasal or subcutaneous injection of a virus vaccine; Mayer (1941) could not confirm the protection experiments. Research workers in this country will no doubt concentrate some of their post-war energy on this vital problem.

Avoidance of exposure is for the urban child virtually impossible, but some recent work suggests that it may be possible to postpone the age of attack. Measles, as Chapin pointed out many years ago, is an infection spread mostly from school. In Philadelphia irradiation of the ceilings of junior classrooms with ultra-violet light apparently prevented the epidemic spread of measles among the irradiated classes (Wells, Wells, and Wilder, 1942). If in this way measles among school children could be shifted from the younger to the older age groups, the chances are that the younger members of the family would be over the age of 3 years before being intimately exposed to infection brought back from school by their older brothers or sisters.

The increasing tendency to admit children with measles to hospital can only be commended if home conditions are such that the child cannot be properly nursed at home, the case removed early, and preference is given to children under the age of 3 years. The respiratory mucous membrane in measles is particularly susceptible to attack by the haemolytic streptococcus and the pneumococcus, and wards are apt to be overcrowded during an epidemic, so that cross-infection, with resulting otitis media and other complications, is more likely to occur in hospital than at home. If measles is to be nursed in hospital, precautionary measures such as adequate ventilation and bed-spacing and oiling of floors and bed-linen must be taken in order to minimize the risk of secondary infection.

Diphtheria.—The value of active immunization against diphtheria is now generally accepted, and the active campaign initiated in 1940 had already by the middle of 1942 resulted in 73% of school children and 58% of pre-school children in Scotland being inoculated; and as deaths from diphtheria in Scotland in the first three-quarters of 1942 were less than half those in the corresponding period of 1940 it seems that the campaign is already producing results. The need now is

to concentrate on the pre-school child and to make inoculation at the age of 1 year a routine social habit for all children. I should like to draw attention to two points:

(1) Infection by the more actively invasive strains (*gravis* and *intermedius*) may occur in the inoculated. Clinically such infections are usually mild, and could be called diphtheritic tonsillitis, for local inflammation without toxæmia is the characteristic feature. But it is well that both doctor and parent should know that prophylactic inoculation does not necessarily mean complete protection. (2) Diphtheria is a difficult disease to diagnose clinically. If there is any doubt, antitoxin should be given as early as possible, and the practitioner should know that with modern refined antitoxin there is little risk of serum reactions. Arrangements should also be made for doubtful cases to be admitted for observation to hospital. On no account must antitoxin be withheld until the bacteriological report on a swab is received.

Scarlet Fever.—A problem requiring careful thought is whether the notification and hospitalization of scarlet fever is at present justifiable when in many instances the only difference between streptococcal tonsillitis and scarlet fever is that the patient with tonsillitis is immune to the erythrogenic streptococcal toxin and the other is not. Scarlet fever is to-day a mild disease, and where conditions are suitable cases could more often be nursed at home, particularly as in hospital the bulk of the complications are due to cross-infection. Forbes (1936) of Brighton showed that at least as many secondary or return cases followed the case isolated in hospital as did the case nursed at home. Another controversial problem which has considerable economic importance is the value of home disinfection after scarlet fever. The furnishings of a room where a case of streptococcal infection has been nursed are likely to harbour haemolytic streptococci, and when the patient leaves it the room should theoretically be disinfected; but Forbes's figures suggest that the patient is the most important focus, and many of the family contacts will already be infected before he is removed to hospital.

If scarlet fever is now a relatively mild infection the haemolytic streptococcus is still the most common pathogen concerned in cross-infection in hospital wards. Most of the complications of scarlet fever and measles, institutional outbreaks of puerperal sepsis, and secondary infection of wounds, and much of the sepsis in E.N.T. wards, are traceable to cross-infection with this organism. The solution of this problem requires a reorientation in our ideas about sources and channels of spread, and much co-operative effort between medical and nursing staff (see Cruickshank, 1942b).

Improvement in Methods of Control

This bird's-eye view of some of the problems in the control of infectious disease suggests that there is much work to be done, and that more efficient machinery is needed for the purpose. A periodic review of the methods for tackling these problems is essential if progress is to be made. Their solution may be considered under the headings of administration, education, structural improvements, and general preventive measures.

Administration.—The health services must be directed by executive and advisory committees, which will deal intelligently and progressively with the problems of public health without having to worry about local rates and taxes. Each community will be larger than that served by many existing local authorities, and preventive medicine will be intimately linked up with other branches of medicine. In each area there must be a field epidemiologist working in close collaboration with an up-to-date laboratory and with his energies directed to tracing causes of morbidity and mortality in various infections, advising about means for their prevention and control, and educating both practitioners and the public to co-operate with him to this end. How much can be done along these lines was exemplified in Rôchdale, where the medical officer of health, with full co-operation from practitioners, instituted a campaign which resulted in a marked reduction in maternal mortality rates. A more precise example has lately been afforded by the work of Bradley (1943) in tracing to a common source apparently unrelated sporadic cases of typhoid fever. Unfortunately, very few of our medical officers have been trained for this kind of work.

As a bacteriologist I am naturally concerned that an adequate laboratory service should be available in all areas and readily accessible to all practitioners. The parent laboratory should preferably be associated with an infectious diseases hospital of at least 150 to 200 beds and resident medical staff. In sparsely populated areas the I.D. block should be within the curtilage of a general

hospital with a joint laboratory, for public health bacteriology need not be divorced from clinical pathology. The essential point is that there should be a real liaison between practitioner and bacteriologist instead of the impersonal postal service which is still too prevalent.

Education.—A most important factor in the control of infectious disease is education of the public in higher standards of personal and public hygiene. This education begins with the pre-school child, and for the purpose there must be a greatly increased number of nursery schools for children between the ages of 3 and 5. At this age the child can be taught good habits and, more important, may be prevented from acquiring the bad habits which are inevitable so long as slum-life is tolerated. At elementary schools more facilities must be given for the growing child to maintain the good habits which it has learned at nursery school. There is not much point in teaching a child cleanly habits, such as washing the hands after using the w.c. or before taking food, while sanitary arrangements at most schools are so unsatisfactory. For more senior pupils physiology must be taught, either by qualified teachers or by the school medical officer, whose duty it is to look after the health and physical development of the child. Incidentally, medical care of the child is a dynamic, not a static affair, and the same medical and nursing staff should be in close touch with the growing child from birth till he leaves school. Further, the sympathy and active co-operation of the teaching profession are essential for the proper discharge of school medical work. Classes in mothercraft should be run at evening schools for adolescent girls and at welfare centres for those who are already parents. A more extended service of health visitors, who must be specially selected and fully trained nurses, would also help in teaching parents the simple rules of hygiene, while the cinema is an excellent medium for health propaganda. Education of the medical profession will include more preventive medicine in the curriculum and frequent refresher courses for those who are already in practice.

Most of us are ignorant of the best methods for disseminating this new health education, and I should like to commend a more general utilization of the Central Council for Health Education, an independent body supported partly by a grant from the Ministry of Health and partly by financial help from local authorities which make use of its facilities. This body has been studying the principles of health education, and has a team of experts who are ready and willing to give help and advice on the many problems of health education and how they can be "put over" to the lay public.

Structural Alterations.—The first essentials are well-designed labour-saving houses in pleasant surroundings for the poorer classes. But with these must go a determined effort to eradicate the slum way of life, which has again been so terribly indicted in *Our Towns*. "Good food is easier to come by than a good home." To lighten the load of the mother with young children day nurseries may have to be continued after the war, although from the point of view of infection they are not unmixed blessings. If they are to prosper, methods for controlling the spread of infection in day nurseries, and, less urgently, in nursery schools, must be devised. Schools need better ventilation, lighting, and spacing, and adequate sanitary arrangements, including wash-hand basins. Hospitals for infectious disease should contain as a minimum 150 to 200 beds, of which upwards of half must be single-bedded chambers for isolation; wards must be small, containing 4 to 12 beds, and be well supplied with wash-hand basins, sterilizers, and the like.

General Preventive Measures.—The most important of these is better nutrition. To that end every mother of a family must have enough money to buy the necessary food, and must be taught what foods to buy and how best to cook them. In this connexion the Ministry of Food is doing a grand job of work, which must be continued after the war. Improved nutrition does not necessarily protect against infection, but when infection occurs its severity is often modified and the risk of complications lessened if the child's general nutrition is good. For example, deaths from measles between the ages of 1 and 2 years are 18 times as frequent among the poorest classes than among the well-to-do, yet measles attacks the poor and the rich alike, and this great discrepancy in mortality must be attributed to the conditions that go with poverty, of which malnutrition is one of the most important.

Improved methods of dealing with water-supplies and sewage have greatly reduced the incidence of intestinal infections. There has been no corresponding diminution in the incidence of respiratory infections, which present a much more difficult problem, although with our newer knowledge a greater measure of control should be possible. Some—e.g., diphtheria, small-pox, and pertussis—can be specifically prevented by prophylactic inoculation, and it may be that influenza and measles will be added to the group. Meanwhile we must consider whether exposure to air-borne infection can be reduced by preventing the spread of infected dust and by the use of aerial disinfectants. Infected dust in hospitals can be controlled by oiling of bed-linen and floors, a procedure which is particularly desirable in wards where there is a considerable risk of bacterial cross-infection (scarlet fever, diphtheria, and secondary infection in measles and influenza). Aerial disinfectants are probably more

applicable to the control of respiratory virus infections, and the extended use of ultra-violet light, or of bactericidal mists and vapours, in hospitals, schools, cinemas, and other places of assembly might reduce the incidence of such common air-borne infections as the cold, influenza, measles, and chicken-pox.

Conclusion

Chadwick was a great sanitary reformer who impressed on our people the close association between poverty, dirt, and infection. In our day, as in his, poverty, dirt, and may I add ignorance, are still the most important contributors to the ravages of infectious disease. He looked forward to the time when sanitary reforms would eliminate the need for doctors. That day is probably still far distant, but meanwhile we can all, by taking thought, help towards making ours a health-preserving as well as a healing profession.

EARLY TREATMENT OF WAR WOUNDS OF THE UPPER PART OF THE FACE*

BY

MICHAEL C. OLDFIELD, D.M., M.Ch., F.R.C.S.

Major, R.A.M.C.; Hon. Assistant Surgeon,
General Infirmary at Leeds

The functions of seeing, breathing, eating, and the expression of emotion may all be seriously compromised as the result of wounds of the face and require surgical restoration. As, however, this paper is confined to the treatment of severe wounds of the upper part of the face, the function of eating need not be discussed further.

First aid in the field or forward dressing stations may first be described. When a high-velocity missile hits a soldier in the face he often feels only a local burning sensation, but he may be knocked to the ground. He then finds blood pouring from his wounds, and this bleeding is often so profuse that it may interfere with his vision or breathing. When he is picked up, a large dressing is, inserted into and over the wound, and the affected part of the face firmly bandaged. This will usually suffice to stop the bleeding, but it is also of importance to shield his blood-stained and horrifying face from the gaze of other soldiers and patients. Though wounds of the face bleed furiously immediately after they have been inflicted, bleeding as a rule stops spontaneously in quite a short time, especially if a large shell-dressing is firmly applied and morphine is administered early. If blood runs back into the mouth or nose and causes difficulty in breathing, the patient is placed on his side or prone on the stretcher.

At the C.C.S., primary operative treatment and transfusion may be necessary. Facial wounds require more thorough cleansing than others because they are never excised and because it is important to avoid subsequent tattooing and "powder marks." They are washed or even scrubbed with soap and water, and irrigated first with peroxide and then with saline or acriflavine. Pieces of dirty clothing, visible metallic foreign bodies, and completely detached fragments of bone are removed. If a fragment of bone is attached to any

* A short address given in opening a discussion upon the early treatment of wounds of the upper part of the face at a conference of medical officers in the Middle East on Feb. 27, 1942.

soft tissue it must not be sacrificed, because it will probably survive, and its removal will be followed by deformity of the framework and contour of the face. In most cases the wound is filled by means of an insufflator with sulphanilamide powder or, better still if obtainable, sulphadiazine or a mixture of sulphathiazole and sulphanilamide. It is then covered with tulle gras and a large pad of saline gauze.

If there is a perforating wound into the mouth with loss of tissue, skin is sutured to mucosa round the edges of the defect. This requires great surgical confidence and courage, and many will be sorely tempted to draw the wound together under tension with a few big stitches, taking wide bites of the skin. That temptation should be boldly overcome, as this is the worst possible surgical treatment. A facial wound should be sutured only if it is recent and there is no skin loss; in which case fine silk stitches are inserted, taking minute bites of the edges but broad bites of the deeper layers of the skin. In this way accurate apposition and eversion are achieved. Stitches in the face are all removed two or three days after their insertion. If this routine is not feasible the wound must be left wide open; for Nature's scar on the face is far preferable to the one which follows meddlesome surgery. A natural scar can always be repaired later by some plastic procedure, but an operation scar with cross-stitch marks is irreparable. It is important to remember also that successful plastic repair can only be assured if the foundations of contour are restored. Defects in facial contour caused by deformities of the bony framework are repulsive because they often produce caricatures of normal expressions. For instance, a permanent grin on one side of the face is grotesque—provoking horror, which a surface-scar line rarely does, though it may be ugly. The first consideration, therefore, in making any "plastic diagnosis" must be the bony framework. This "plastic diagnosis," so often stressed by Gillies, is the estimation of displacement, or loss of tissue, first in the bony framework or contour supports, secondly in mucosal linings, and last of all in the skin covering. Moreover, the first stage in plastic treatment consists in planning beforehand the order and method of replacement of lost tissue or realignment of normal tissues, in relation also to the framework, lining, and covering of the face.

In applying these principles of plastic surgery four special areas may here be considered: the forehead and frontal sinuses, the orbital region, the nose and ethmoid sinuses, the cheek and maxillary antra.

Forehead and Frontal Sinuses

Wounds of the upper part of the forehead, when associated with fractures of the skull, are treated by the general surgeon or neurosurgeon in the early stages, but cases are often referred some time afterwards to the plastic surgeon, for repair of a deeply cupped scar of the forehead following a depressed fracture. In the plastic treatment of these cases scars are excised and the skin flap is most carefully separated from the underlying dura. The margins of the bony defect are defined on both surfaces. A suitably curved segment of the inner table of the iliac bone, with the smooth concave inner face towards the dura, is then inserted into the defect and fixed in position by stainless-steel-wire sutures. The skin flap is replaced after the contour has been repaired.

In treating a recent wound of the lower part of the forehead involving the frontal sinus, the posterior wall of which is intact, it is advisable to remove all loose fragments of bone and clot from the sinus and to drain it into the nose through a small rubber tube surrounded by a razor-graft taken from the inner arm. In a few cases the forehead wound may then be closed without external drainage, but in most gunshot wounds with severe comminution and loss of tissue this is impossible and the wound must be left wide open.

When the posterior wall of the frontal sinus is fractured and the dura torn, repair of the dura by a fascia lata graft, using a transfrontal approach, is necessary, and the case should be transferred at once to the care of a neurosurgeon.

Orbital Region

In the orbital region, plastic surgery starts after the ophthalmic surgeon has examined the eye and when he has carried out any treatment necessary for the eye itself. In fact,

close co-operation with the ophthalmic surgeon is essential during all stages of plastic repair. Wounds of the orbit will be discussed under the headings of deformities of the bony margins, and deformities involving the soft tissues—i.e., eyebrows, eyelids, eyelashes, and the eye-socket.

Bony Margins.—If portions of the orbital ridges are displaced they should be reduced as soon as possible even if quite loose. If any soft tissue remains attached to these fragments the bone must be retained. On the other hand, if there has been loss of bony tissue or a long delay in replacement it is usually wise to insert a small iliac-bone graft. When the supra-orbital margin is missing the graft is inserted through an incision in the eyebrow; when the infra-orbital plate is defective an incision is made behind the hair line in the temporal region.

Eyebrows are replaced by Wolfe grafts from the post-auricular region on the same side. In making the bed to take these grafts, a small triangle of scar tissue is excised from the medial extremity of the wound and the outer angle is tapered. It is most important to implant the graft so that the hairs are growing downwards and outwards, and it is also wise to warn the patient that the hairs transferred in the graft will all fall out, but will be replaced by others in three months' time.

Upper eyelashes are made by a Wolfe graft from the opposite eyebrow, the lower lashes from the eyebrow on the same side.

Eyelid deformities without severe loss of tissue may be repaired most satisfactorily by excision of the scars, division of all adhesions, and then sliding lateral flaps so that one is fixed above the other. Vertical suture lines in the eyelids should be avoided, and subcuticular catgut stitches are generally used. When, however, there is a severe loss of eyelid skin causing ectropion—for instance, after a burn—skin-grafting is always indicated. In second- or third-degree burns of the eyelids, razor-grafting associated with tarsorrhaphy should be undertaken as soon as possible as an emergency procedure to prevent corneal ulceration. When ectropion results from scar contracture in burn cases, Thiersch grafts should be applied on accurately fitting Stent moulds for the upper lids, and the inner side of the upper arm is the most suitable donor site. When used for the lower lids, however, this type of graft tends to look rather pale or parchment-like. A Wolfe graft taken from the back of the ear gives the best results for the lower lid. When ectropion is established, both upper or both lower lids may be grafted at the same operation, but it is rarely possible to obtain the necessary over-correction if the upper and lower lids on the same side are grafted on the same occasion, except in a patient who has been recently burnt. In burn cases it is most important to over-correct the ectropion and to divide all adhesions, and it is wise to let in one and a half to twice the area of skin which appears to have been lost. In burn cases the usual mistake is under-correction; over-correction is extremely rare. Contraction of the graft occurs always, but "puckering of the graft" may be prevented if grease massage is started 10 to 14 days after operation.

When the eye has been lost and the remaining socket is too small to retain an elegant artificial eye an epithelial inlay is advisable. After the remnants of mucosa have been excised a new skin-lined socket is made by burying a thin razor-graft which is draped over a disk-shaped gutta-percha mould perforated in the centre.

Deformities of Nasal Contour, with Damage of Ethmoid Sinuses

In modern warfare, when armoured vehicles often capsized and motor-cycles collide, serious blows on the centre of the face are common, and result in various types of deformity of the nasal contour frequently associated with damage to the ethmoid sinuses, and a variety of facial wounds.

Fracture of the nasal bones and nasal processes of the maxillae may result from: (i) a direct or forward blow on the bridge of the nose causing it to cave in; (ii) a lateral blow causing lateral deviation and comminution of the nasal processes; (iii) an upward blow on the under-surface of the tip of the nose which results in telescoping of the bridge and septum.

In practice, a combination of two or three of these types of injury is quite often seen in one patient.

The optimum period for replacement of the nasal framework is within 48 hours of the injury, but it can be undertaken quite satisfactorily within four days. Under intratracheal anaesthesia, disimpaction is carried out by the Gillies-Kilner technique. Using Walsham's forceps, both nasal processes are everted, then the septum is straightened and the nasal bones are elevated with Ashe's forceps. Finally, the nasal processes are pressed inwards and the bridge is narrowed. This position is maintained for four to six days by a Safian brace, or by the St. Louis type of mattress suture. Later cases of traumatic nasal deformity require intranasal refracture by means of a Safian saw or a chisel. When the saddle deformity is persistent a small iliac-bone graft is inserted through a columella-splitting incision. Rib cartilage is not suitable for this purpose because it occasionally bends in a most disconcerting manner some months afterwards.

More violent blows on the front of the face cause a circular depressed fracture of the maxillary block. The centre of the face "caves in" and a "dish-face deformity" results. If this is not reduced the patient has a permanently sad expression with hollows under the eyes, and the base of the nostrils sinks inwards, giving the face a negroid appearance. Minor "dish-face" deformities can be reduced by gradual elastic traction applied to the sunken maxilla through upper dental splints by means of a headcap bearing an anterior bar. Severe "dish-face" deformities are often associated with fractures of the base of the skull through the cribriform plate and comminution of the ethmoid cells. Cerebrospinal rhinorrhoea may result and there is a danger of meningitis. In the past it was thought to be advisable to wait until the patient was out of danger before attempting reduction, but usually by this time reduction was impossible. Immediate and forcible reduction with lion forceps has been suggested in some of the cases. Cone and the Montreal school of neurosurgeons in certain cases of cerebrospinal rhinorrhoea advise direct repair of the torn dura from above, using fascia lata and a transfrontal approach.

Wounds and Associated Deformities of Cheek and Maxillary Antrum

The malar bone and zygomatic arch take the full weight of all blows upon the cheek. A blow from the front, if severe enough, drives the malar inwards through the anterior wall of the antrum. The body of the malar, being very strong, is rarely fractured, but its zygomatic, frontal, orbital, and maxillary roots are commonly injured, with the result that the bone itself is not only depressed but also rotated downwards. A severe blow on the side of the face causes the zygomatic arch to cave inwards. Unless seen on the day of the injury, before the swelling of the cheek has occurred, these deformities are usually missed. The symptoms and signs to look for in these cases are: (1) Bleeding from one side of the nose due to haemorrhage into the antrum. (2) Diplopia due to depression of the orbital plate. (3) Pain and numbness in the distribution of the infra-orbital nerve. (4) Bruising of the cheek and subconjunctival haemorrhage. (5) Flattening of the upper part of the cheek, a hollow under the eyes, and fullness of the lower part of the cheek. There is usually a notch palpable on the infra-orbital margin. (6) Interference with mastication is not uncommon. It is due to pressure of the displaced zygomatic arch upon the coronoid process or injury to the temporal muscle near its insertion. This may cause pain on chewing, slight trismus, or, on opening the mouth, deviation of the lower jaw to the opposite side, a position which appears to be one of mandibular rest.

Depressions of the malar or zygomatic arch without an associated external wound are common in mechanized warfare. They should be elevated with a lever as soon as possible, preferably within three weeks of the injury, by the Gillies approach through an incision within the hair line of the temporal fossa.

In later cases a combined temporal and buccal approach is often required. The malar bones require fixation after operation by a sulphanilamide and vaselined-gauze pack in the antrum or by external pin fixation. In the most severe deformities in which there has been loss of bone an iliac-bone graft is inserted behind the cheek through a temporal incision.

Conclusion

Six elementary principles in the early treatment of wounds of the upper part of the face may be emphasized:

- (i) Cleanse the wound most thoroughly with soap and water, peroxide, and saline.
- (ii) Never excise a facial wound.
- (iii) Save the framework of the face even if it is loose; sacrifice a bony fragment only if it is completely detached from all the surrounding tissues.
- (iv) If there has been any skin loss, pack the wound with sulphanilamide powder and leave it open.
- (v) If there has been no skin loss and the wound is recent, insert fine silk stitches and remove them within three days.
- (vi) In the face, never insert a few big stitches under tension; they usually lead to serious septic complications and will always be followed by an irreparable scar, which will remain a disfigurement for life.

I am indebted to Major-Gen. D. C. Monro and Brigadier W. H. Orlivie, consultant surgeons, M.E.F., and Colonel R. R. G. Atkins, officer commanding a general hospital, for permission to publish this discussion. I shall always be grateful to Sir Harold Gillies and Mr. T. Pomfret Kilner, the pioneers of British plastic surgery, for teaching me these principles, which I hope I have interpreted correctly.

SPECIFIC GRAVITY OF THE CEREBROSPINAL FLUID

WITH SPECIAL REFERENCE TO SPINAL ANAESTHESIA

BY

W. ETHERINGTON-WILSON, F.R.C.S.

In 1932, after many months of exhaustive experiments with glass spinal canals (mock spinal analgesia: Etherington-Wilson, 1934, 1935), I came firmly to the conclusion that the best single method of control and accuracy in all types of spinal nerve-root block lay in the technique of *timed vertical ascent*. As time passed, this work has had recognition, and is now known as the Etherington-Wilson technique. Prejudice against the use of hypobaric solutions in the sitting-up position was widespread all over the world, but this boggy has, I believe, in some measure been allayed. Such a technique, however, demands knowledge of the specific gravity of the cerebrospinal fluid in normal individuals and in pathological conditions, and also that of the solution injected. If these two solutions vary to any great extent it might be supposed (rightly) that the technique will not always be reliable. The solution supplied (like nupercaine and others) is, however, of known specific gravity. Cerebrospinal fluid is alleged to have markedly varied readings: extravagant differences are quoted—1.004 to 1.012, and even greater diversities. If such estimates were arrived at by some form of small hydrometer, or there was delay in testing, or no account was taken of the temperature of the fluid at the moment, then such computed answers were inevitable. My experience of the use of a small hydrometer of the usual type was one of difficulty and error: repeated examinations of a single specimen of cerebrospinal fluid would register wide disagreement.

These variable quotations have passed from book to book and have been used in criticism of my technique in spinal nerve-block. Experience of results in over 1,500 spinal anaesthetics did not bear out the truth of such ready, unpractised judgment. In short, the assertion comes rather as a challenge and a stimulant, and involves a duty. Hence the investigation which follows. Contact with others suggests that many anaesthetists still accept the idea that the sp.gr. of the c.s.f. *in situ* at body heat produces an average figure of 1.007 to 1.008. This is not even near the truth, and sp.gr. is, of course, of some importance in certain forms of spinal nerve-block. The sp.gr. of the c.s.f. was tested in 314 consecutive cases, at all seasons of the year, during seventeen months, a great variety of individuals being represented.

Specific gravity beads, carefully tested and cared for, were used for the purpose. All estimations were done personally, the first few being discarded until I felt that some of the tricks, if any, had been mastered. One person only in the theatre occasionally checked the results. Patience, some adeptness, and experience had to be acquired to get results, allowing for a possible margin of error in temperature represented by a reading of 1° F. when using a solution thermometer. A clinical thermometer was also used on occasions as a check, for beads within its range of calibration. As an additional and comparative means of securing accuracy different bead tests were carried out on each specimen.

Apparatus

The specific gravity beads used ranged from 1.000 to 1.008; and each had a distinguishing colour. The greatest care was taken to keep clean and well washed, after use, in distilled water. The same applies to the test-tubes and thermometer. A special rack of six narrow test-tubes having an internal diameter of 3/8 to 1/2 in. were found most useful. They allowed of the collection of 2 c.cm. or less of c.s.f., which rises to a height of about 1½ in. up the tube. Each tube is closed after filling. Four numbered corks were kept on the rack for this purpose. All tubes were dry before use. When not in use, and after cleansing and drying, they were kept locked up and stoppered. A wide-scale Fahrenheit thermometer, tested for accuracy, very narrow, and much longer than the test-tube, was used throughout without change. The end containing the mercury should be of short length. A magnifying glass, apart from its obvious use for noting the thermometer markings, is necessary for watching the bead movements. Hot- and cold-water taps were utilized for heating and cooling the c.s.f. in the test-tubes when trying out a series of beads. Iced water was also used for the heavier beads, but, apart from interest and as a check-up, is not essential. All specific gravities were carefully recorded, with notes appropriate to the case—e.g., age, sex, general condition, pathological state, high blood or c.s.f. urea or sugar or bile, repeated estimations, etc.

Method of Estimation

Cerebrospinal fluid was allowed to drip into the narrow test-tube. The latter was corked if not immediately tested, but all estimates were carried out within 3 to 4 hours. In the series of 314 cases an average of three different beads was used for each fluid. In a great number of cases many more beads were required—as many as eight for one specimen. An average time of 15 to 25 minutes was taken over the testing of each fluid. The use of more than one bead in each test was of course of value as a check against slight errors. Thus, in the average, it was found that with a specimen of c.s.f. at 91° F., 91° F., 83° F., and 74° F. the sp.gr. recorded by the beads was 1.003, 1.004, 1.005, and 1.006 respectively. The sp.gr. was judged correct when the bead remained absolutely motionless, floating and away from the bottom or upper level of the fluid. This is confirmed by tapping or shaking the tube to move the bead and watch its behaviour. When motionless the thermometer, which has been held in the fluid all this time, is immediately read.

Before any readings are begun care is necessary to allow the bead to get well "soaked" in the c.s.f., and any bubbles adherent are easily dislodged by a sharp shake or tap of the test-tube. In many suitable cases the c.s.f. was used for inquiry into the sugar, urea, chloride, and protein content.

Types of Cases

As much variety of individual and circumstance as possible was hoped for and obtained in this consecutive series of 314 cases, spread over from Oct., 1942, to Feb., 1943. Ages varied from 2 and 5 years to 88 and 90 years (see Table). The table also shows the details of sex, healthy or ill, hospital or private patients. Among these cases were local people, some from other parts of the country, foreigners, soldiers; tall, short, thin, obese. Some were well, others suffered from such diverse conditions as pyrexia (various), wasting, anaemia, various degrees of blood loss, emergencies, jaundice, alcoholism, dieting, inoperable carcinoma (abdominal), intestinal obstruction—early, late, and moribund—tuberculosis, early and full-term pregnancy, ascites, vomiting, diabetes, chronic high or low blood pressure, high blood urea, megacolon, gastric stasis, head

injuries, otitic hydrocephalus; some received glucose-saline or blood transfusions. Twenty patients had a second lumbar puncture, at times varying from two days to a few weeks to many months; a second examination of the fluid was carried out for comparison.

Table of 314 Cases

Age :	1-9	10-19	20-29	30-39	40-49	50-59	60-69	70-79	80+	Hosp. Cases	Private Cases	Healthy	Ill	Multiple Myeloma
Males (142)	2	9	8	16	16	32	34	22	3	-	-	-	-	-
Females (172)	1	12	17	28	32	29	34	15	4	-	-	-	-	-
Total (314)	3	21	25	44	48	61	68	37	7	225	89	194	120	20

Results

In this series it was found, in spite even of pathological states which affect the c.s.f., that the sp.gr. of the latter varies only very slightly. From the spinal anaesthetist's point of view the small difference can be disregarded. The ascent of a solution up the spinal canal is but little quickened if the sp.gr. of the c.s.f. is 1.004 at body temperature instead of the average 1.003+. In no patient in this group (apart from big sugar, high urea, or deep olive malignant jaundice) was much appreciable difference noted, and no case was found to have a sp.gr. of 1.004 at normal body temperature. The uniformity of result was so monotonous that I was able to demonstrate that the temperature of the c.s.f. could be forecast when the bead was suspended in midstream and resting. From this lot and continuous series of cases the following points were extracted.

1. The sp.gr. of the c.s.f. at any given temperature is remarkably constant.

2. Variations do occur, but they are slight and are found especially in cases with high c.s.f. sugar. An occasional healthy individual, be he old or young, may show a sp.gr. greater or less than the average (9 cases in 314). Such variations (except in the high sugar content) do not amount to a whole point (i.e., 1.003-1.004). Unfortunately I have not had the opportunity of testing a case in which the c.s.f. sugar was more than 90 mg. per 100 c.c. It was clear, however, from my three diabetic cases in this series that sugar is the most potent cause of the rise in specific gravity. Such a rise will not be found excessive even probably with a content of 200 mg. per 100 c.cm. Moreover, such a case would not knowingly be subjected to operation.

3. Other conditions in which a detectable change was noticeable by means of the bead estimation were:

(a) High blood or c.s.f. urea.—Nine such cases were examined, the highest urea being 428 mg. The sp.gr. was slightly increased in 3 cases but much less marked than in high-sugar cases.

(b) Glucose-saline intravenous drips in two out of six cases showed a slightly higher sp.gr. The remaining four, two or which had blood transfusions, were normal.

(c) Severe vomiting with some dehydration raised the sp.gr. figures in one out of four cases; one case also showed a lower estimate.

(d) Severe blood loss or marked anaemia lowered the probable average sp.gr. slightly.

(e) Intense olive jaundice (malignant), with a tinged cerebrospinal fluid, showed a rather lower sp.gr. than normal in three cases. In other cases in which jaundice was not so marked did not reveal any change.

(f) The lowest reading obtained in the series of 314 cases occurred in a rare surgical condition which will be recorded elsewhere. A man aged 52, on whom I did a gastro-jejunostomy twelve years ago, developed a retrograde acute jejuno-gastro-intussusception in 1942. Diagnosis was easy, being the second attack, operation prompt, and recovery uneventful. Retching vomiting had been severe, but not prolonged enough for dehydration in such a case. No explanation is forthcoming to explain the lowest sp.gr. of the series, which was nearly a whole point variance with the normal average.

In one case of each of the following conditions there was no change from the average sp.gr.: cerebral tumour, cerebral spinal myelitis, and early tuberculous meningitis (c.s.f. protein mg.). Seven c.s.f. specimens were blood-tinged. Twenty lumbar puncture specimens were the same as the first estimations. Attempts to show tendencies to vary owing to age and sex were inconclusive. All that can be said is that in males a larger number of slightly higher specific gravities will be met with than in the females.

gr. was identical in three individuals aged 2, 5, and 90 years—the youngest and oldest of the cases. Apart, possibly, from an undiscovered very high c.s.f. sugar content, no noteworthy change is presented in the c.s.f. specific gravity from the pathological conditions which have been specified. From the spinal anaesthetist's point of view, and especially for those who use a timing technique, such a report may be reassuring.

Conclusions

The specific gravity of the cerebrospinal fluid at normal body temperature remains between 1.004 and 1.003, and is rather 1.003.

The constancy was remarkable in a consecutive series of 14 cases of great variety.

The usual pathological states of the c.s.f. which may be met with can be ignored when spinal nerve-block is contemplated. Much more so is this the case in the healthy subject.

In an experience of over 1,500 spinal anaesthetics by my timing technique there has been no case of loss of control of the ascending hypobaric solution (nupercaine and spino-sine). It has therefore not been any surprise to find that the c.s.f. of the c.s.f. varies in but small degree.

I have to thank Dr. H. A. Fielden for the pathological work at the Torbay Hospital laboratory; and to my anaesthetists, Drs. R. A. Attey and M. Lambie, I am grateful for the collections of cerebrospinal fluid.

TRAUMATIC ARTERIAL SPASM*

BY

C. W. CLARK, M.D., Ch.M., F.R.C.S.Ed.

The interest created in recent years in this subject by a number of writers—notably, Griffiths (1940), Barnes and Trueta (1942), and Cohen (1940-1)—has prompted me to report this case of traumatic arterial spasm, associated with a closed fracture of the tibia and fibula in the middle third resulting in gangrene and amputation.

Case Report

A gunner aged 30 was struck on the antero-lateral aspect of the middle third of the right leg by a gun limber at 9 a.m. on Feb. 25, 1942. He was admitted to hospital approximately six hours after injury with the leg in a Thomas splint, with traction from his boot to the foot of the splint. X-ray plates revealed a fracture of both bones of the leg in the middle third with practically no displacement. He was taken to the operating-room, where inspection of the leg revealed some swelling at the site of fracture. The patient complained of severe pain at and below the site of fracture, and was given morphine gr. 1/4. He had been given morphine gr. 1/4 an hour and a half before admission.

Under pentothal and cyclopropane anaesthesia the Thomas splint and boot were removed. The circulation in the foot and toes appeared normal, judged by colour and warmth, but no attempt was made to feel pulsation in the dorsalis pedis or posterior tibial arteries. There was no wound or sign of injury in the whole limb aside from the swelling at the fracture site. A Steinmann pin was inserted through the os calcis and, with moderate traction of 15 lb. on a Braun splint with a well-padded wooden cross-bar against the junction of the middle and lower thirds of the thigh, a skin-tight plaster was applied from the toes to the tibial tubercle, incorporating the Steinmann pin. This took only about 15 minutes, and then the traction was released and the plaster carried up to the groin with the knee in flexion. The limb was then placed on a Braun splint with 7 lb. traction, the foot of the bed being elevated.

During the night the patient complained of severe pain in the leg, and was seen by the duty medical officer. There was no swelling of the toes and the circulation appeared normal. He required two injections of morphine gr. 1/4 during the night for severe spasmodic pain in the leg at and below the fracture site.

At 9 a.m. on Feb. 26 the cast was bivalved because of his complaints of pain, and the anterior half removed, leaving the posterior half as a back splint. The circulation in the toes appeared normal, but there was no pulsation in the dorsalis pedis artery. He had anaesthesia from the site of the fracture, distally involving the toes, and had no movement in the toes. At this time he claimed that the foot and toes had felt "dead" immediately after injury. No

sign of any pressure or tightness of the cast on the limb was observed.

At midnight on Feb. 26—39 hours after injury—the anterior tibial compartment seemed to be considerably swollen and tense, but the colour of the toes and the circulation in them appeared satisfactory. He was taken to the operating-room and the anterior tibial compartment was opened by a vertical incision. The muscles were somewhat greyish in colour and did not contract on stimulation. The anterior tibial artery was exposed, and was found to be contracted and pulseless. The artery was stripped of surrounding areolar tissue and freed through most of its course right up to the foramen in the interosseous membrane. Pulsation did not return after this procedure. There was no sign of injury to the artery, and no haemorrhage in the anterior compartment had occurred. The wound was left unsutured, with vaselined gauze dressing.

On Feb. 27 the degree of circulation to the toes had notably decreased; the toes were very cold and somewhat cyanotic, and the anaesthesia remained as previously described. He had a temperature of 101° F. and was still complaining of excruciating pain in the foot and leg.

He was taken to the operating-room again and excision of the dead muscles of the anterior tibial compartment was performed. The muscles were very grey and were obviously completely dead, with no response to stimulation. The only ligature applied was to the anterior tibial artery, which had a very slight ooze from it prior to application of the ligature. The wound was left open, with vaseline packing. At the time of operation the foot had a cadaveric appearance. A posterior incision was made at this operation to determine if the same condition had occurred in the posterior part of the leg. The gastrocnemius contracted readily on stimulation, so the wound was closed.

On Feb. 28, at noon, the toes were discoloured and definite gangrene was present in the foot. The temperature was 101° and the pulse 110, and the patient was still complaining of excruciating pain in the leg in spite of repeated doses of morphine. Amputation was done in the thigh, with a 12-in. stump. No tourniquet was used, and only four ligatures were necessary. No pulsation was present in the femoral artery just above the adductor tubercle, and the artery was very contracted. It was divided above this point, where pulsations could be felt. There was no sign of any injury in the tissues of the thigh or to the femoral artery itself.

Immediate dissection of the amputated leg revealed that the femoral, popliteal, posterior tibial, and peroneal arteries were contracted to the size of a fine string—about one-quarter their normal diameter. The vessels were carefully dissected and opened into their smaller branches; no sign of thrombosis or injury was present in the arteries or veins. There was a slight haemorrhagic exudate along the posterior tibial vessels and nerve. The muscles in the posterior compartment had degenerated. The superficial part of the gastrocnemius was only very slightly greyish in colour, whereas the deeper muscles were markedly grey and degenerated.

The stump healed by first intention and the patient made an uneventful recovery.

Comments

It would appear that this patient had persistent and extensive arterial spasm, affecting not only the main vessels but also the collaterals to such a degree that it resulted in massive death of muscle tissue first, followed by gangrene of the limb, necessitating amputation three days after the original injury. There was absolutely no sign of injury to the femoral, popliteal, tibial, or peroneal vessels. The sympathetic reflex vasospasm set up at the time of injury to the antero-lateral aspect of the leg in the middle third was not relieved by stripping of the anterior tibial artery.

No forcible distraction or manipulation was necessary, and Böhler's frame was not used. It is highly improbable that the method of maintaining position during application of the plaster could have aggravated the vasospasm.

On removal of the plaster there was no sign of pressure or tightness of the cast at any point.

Even after amputation, 75 hours from the time of injury, the vessels on dissection were still in a marked state of spasm.

The symptom of excessive pain on admission of a well-splinted fracture should make one suspicious of traumatic arterial spasm.

The aetiology and treatment of arterial spasm have been adequately dealt with in the references quoted, and a detailed discussion would be out of place in this case report.

A COMMON CAUSE OF DIARRHOEA, VOMITING, AND DEHYDRATION IN INFANTS

BY

PERCIVAL W. LEATHART, M.B., B.Ch.

*Surgeon to Ear, Nose, and Throat Department, Royal Liverpool
Children's Hospital*

Disease in infants is frequently characterized by diarrhoea, vomiting, and increasing dehydration. Sometimes this condition is due to gastro-enteritis, proved by the discovery of a causative organism in the stools and post-mortem appearances in the intestine. More often, however, no causative organism is discovered, and at necropsy no abnormality is found in the intestine. It is obvious, therefore, in this type—and it is exceedingly common—that the diarrhoea, vomiting, and dehydration are not due to gastro-enteritis, and that such a diagnosis, if made, is incorrect. The object of this communication is to point out a condition in this type of case which, though frequently unsuspected, is commonly present, to describe how it is acquired, and to give reasons for the belief that it accounts satisfactorily for the symptoms.

It is well known that at post-mortem examinations on children who during life had suffered from diarrhoea, vomiting, and dehydration an unsuspected purulent mastoiditis is frequently discovered on both sides. As an explanation it has been suggested that the mastoiditis is a terminal event. But since mastoiditis, if present, as will be shown later, can be diagnosed with certainty two or three weeks before death, this explanation is unconvincing. We are forced, therefore, to the conclusion that many infants dying from diarrhoea, vomiting, and dehydration have had in addition an unsuspected bilateral mastoiditis two or three weeks before death.

Method by which Mastoiditis is Acquired

The Eustachian tube in infants is more horizontal than in adults and, as in them, opens with each act of swallowing. When the child is lying on his back the tube is perpendicular, so that when open, as in swallowing, any foreign liquid in the post-nasal space is free to pass by gravity and suction into the tympanum and mastoid antrum—in this way milk, vomit, or infected mucus is offered an easy entrance. It is well known that a majority of infants suffering from severe diarrhoea, vomiting, and dehydration are well under 1 year old—too young to sit up—and are bottle-fed, often while lying down, in an ideal position for milk or any other liquid to reach the mastoid antrum through the Eustachian tube by gravity and so cause a mastoiditis. Diarrhoea, vomiting, and dehydration, and therefore mastoiditis, however, are not confined to children who cannot sit up and are bottle-fed. It frequently happens that a child who is in hospital suffering from some air-borne infection, after having recovered from it develops diarrhoea, vomiting, and dehydration. These children have been too ill to sit up, so that infected mucus or liquid food vomit in the post-nasal space can easily enter the mastoid cavity, infecting it in the same way.

We may conclude, therefore, that mastoiditis is commonly caused by milk, vomit, or infected mucus entering the Eustachian tube in children who are either too young or too ill to sit up, and are accordingly nursed and perhaps fed while lying on their backs.

Pathology of Diarrhoea, Vomiting, and Dehydration due to Mastoiditis

We have come to the above conclusion that gastro-enteritis is not the cause of diarrhoea, vomiting, and dehydration because this condition is not present. That mastoiditis is the cause is based upon the fact that after operation these symptoms have often rapidly disappeared. The tympanic membrane and mastoid antrum are supplied by parasympathetic nerves from the seventh and ninth cranial nerves. When these nerves are inflamed the nerve endings are stimulated, causing a parasympathetic reflex whose afferent limb travels in the seventh or the ninth nerve, the efferent limb in the tenth, which applies the intestine with secretory fibres. The normal balance between parasympathetic and sympathetic innervation

is upset in favour of the parasympathetic, leading to hypersecretion, evidenced by diarrhoea, vomiting, and dehydration.

Diagnosis

We must remember that an infant cannot tell us that he has earache; that it is impossible to find out by pressure over the mastoid whether he has pain or not; that discharge from the ears is seldom present; that examination of the tympanic membrane is often impossible, and even when a view is obtained the appearances may be equivocal; and, finally, that only very rarely is there a swelling behind the ear. In fact none of the ordinary physical signs associated with acute mastoiditis in elder children is present. Yet in addition to diarrhoea and vomiting a careful examination will elicit additional symptoms and physical signs which allow a diagnosis of mastoiditis to be made with certainty. Perhaps a recent rise in temperature has been noticed; the child has begun to cry out as if in pain; he puts his hand to his head and rolls his head on the pillow, causing a bald patch on the back of his head. On rare occasions a discharge appears from one or both ears. The tympanic membrane, if seen, may be pinched or may lack the normal lustre. Almost invariably the lymph nodes in the posterior triangle of the neck are enlarged so that they roll under the finger. This is the most significant physical sign, and is of greater diagnostic value than the appearance of the tympanic membrane.

It may be said with confidence that if a child suffering from diarrhoea and vomiting has enlarged glands in the posterior triangle and has in addition some of the above physical signs a mastoiditis is present. If this child is losing weight and going downhill in spite of sulphonamides and intravenous salines a mastoid operation is urgently required to save his life. It is not suggested that all cases suffering from mastoiditis require operation; many recover spontaneously, probably helped by sulphonamides and certainly by intravenous saline and blood transfusion. In a certain number, however, if mastoiditis is progressive, and these patients, unless treated surgically, will inevitably die.

Prevention

It has been shown above that mastoiditis occurs chiefly in bottle-fed infants who, being too young to sit up, are fed lying down, and also in elder children suffering from air-borne infection or other illness which has rendered them too ill to sit up. On this account such children have been nursed and perhaps fed in the recumbent position—a position which invites mastoid infection by liquid food, vomit, or infected mucus passing through the Eustachian tube. It is therefore suggested that children should never be fed while lying down, nor should they ever be allowed to lie for a long time on their backs; they should be propped up in bed and constantly changed from side to side if too young or too ill to do so themselves.

The operation in itself is an extremely simple one and can be completed on both sides in about 15 minutes. If the child has no air-borne infection light ether anaesthesia is satisfactory but should there be bronchitis or pneumonia or a suspicion of any form of pneumonitis a local anaesthetic should be given. It must be stressed that the condition, as its aetiology suggests, is nearly always bilateral, and that the best results are achieved by opening both mastoids at the primary operation.

Conclusion

It would appear relevant to state that the remarks made above are the result of work done chiefly at the Royal Liverpool Children's Hospital in co-operation with the physicians and surgeons during the last 20 years. During this period more than 2,000 cases of progressive mastoiditis have been selected for operation; all of them were obviously going downhill, and in the vast majority mastoiditis was proved at operation. Without surgical aid all would have died; after operation approximately 80% recovered. It is clear, therefore, that early operation between physician, general practitioner, and auricular surgeon more complete and more universal the death rate among infants would be materially reduced, possibly even halved. It is stressed that when diarrhoea, vomiting, and dehydration is due to progressive mastoiditis the condition cannot be cured by sulphonamides, intravenous salines, or changes of diet.

Medical Memoranda

Plantar Dislocation of the Fourth Metatarsal

Dorsal dislocation of the head of a metatarsal bone is not infrequently encountered in orthopaedic and surgical practice, but plantar dislocation appears to be uncommon and almost unique. A diligent search of the literature has failed to disclose any report on such a case, and the condition is not mentioned in any of the standard orthopaedic textbooks consulted. The following example came under my observation in Oldmill Hospital, Aberdeen:

CASE REPORT

A soldier aged 28 was admitted to hospital complaining of pain and swelling in the sole of the foot, aggravated by walking. He gave a history of having been at a dance four days previously, and, while leaving the hall, having "slithered down two stairs," landing on the "ball of his right foot." He felt a sudden sharp pain, but was able to walk without much inconvenience for the rest of the evening, and reported for duty as usual next day. At the dance he was wearing light-weight patent-leather shoes of the usual type. During that afternoon he began to complain of a dull pain in the sole of the left foot, which had become somewhat swollen. On the following morning—that is, on the second day after receipt of the injury—he reported to his M.O., who considered that he had a strained ankle. Two days later he was admitted to hospital.

Examination upon Admission.—The patient was a well-built young man in good general health. No abnormality was detected other than the local condition in the left foot. The appearances here were interesting. The foot showed a moderate degree of swelling, and on the bases of the four small toes on their dorsal aspect there was slight bruising, mostly on the outer side. A space was palpable over the head of the fourth metatarsal bone and slight crowding together of the third and fifth toes, which slightly overlapped the fourth. Movement of the toes was quite free. On the sole of the foot was a definite swelling, hard, smooth, regular, fixed, round, localized, and tender. It was diagnosed as the head of the fourth metatarsal dislocated plantar-wards. X-ray examination confirmed the diagnosis. The condition was irreducible by manipulation, so open operation was decided upon.

Operation.—This was done under gas, oxygen, and ether anaesthesia. The usual skin preparation for a bone operation was carried out and a tourniquet applied. An incision was made parallel to the outer border of the foot, in the line of the metatarsal, centred over the head, and with two-thirds of the incision proximal to the line of the metatarsophalangeal joint. The deep fascia was incised and the head exposed. It was embraced by the second and third tendons of the flexor digitorum brevis, by the third lumbrical, and by the third tendon of the flexor digitorum longus, and lay superficial to the transverse head of the adductor hallucis. The tendons were gently retracted and the head levered back into the joint. The capsule was rent, but had not contracted enough to prevent this manoeuvre being successfully effected. The wound was then closed by a few skin sutures and a firm bandage applied.

Post-operative Period.—This was uneventful. Radiography showed the head to be reduced, and clinically the foot resumed its normal anatomical appearance. Swelling subsided, pain was completely relieved, and the wound healed by first intention. After two weeks the foot was allowed to bear weight, and massage and exercises were carried out on the muscles of the calf and leg. In four weeks recovery was complete, and the patient was discharged to a convalescent depot.

DISCUSSION

The mechanism of this injury is hard to explain, and the patient was not helpful in describing exactly what happened when he slipped. That of course is understandable. It was established, however, that he slipped down two steps and abruptly landed on the ball of the affected foot. He considers that his toes were fully "cocked up" at that time and that he leaned forward to recover his balance. It may be possible that full dorsiflexion of the toes accompanied by violent forward swinging of the body on the fixed foot may slip the head of the metatarsal out of position; but this is improbable, and the explanation is unconvincing.

The other foot was completely normal, and there was no reason to suspect weakness of the transverse ligament of the heads of the metatarsals. In short, the mechanism was not worked out to one's satisfaction, but it is felt that the condition is rare enough to merit being reported.

I am indebted to Dr. Harry J. Rae, superintendent of Oldmill Hospital and Medical Officer of Health for Aberdeen, and to Mr. Andrew Fowler, consultant surgeon to the hospital, for permission to publish this clinical memorandum.

GEORGE B. MAIR, M.D., F.R.C.S.,
Surgical Registrar,
Oldmill/Woodend Hospital, Aberdeen.

Reviews

PSYCHONEUROLOGY AND ENDOCRINOLOGY

The 1942 Year Book of Neurology, Psychiatry, and Endocrinology. Neurology, edited by Hans H. Reese, M.D.; Psychiatry, edited by Nolan D. C. Lewis, M.D.; Endocrinology, edited by Elmer L. Sevitzhaus, M.D. (Pp. 768.) Chicago: Year Book Publishers.

The Year Book of Neurology, Psychiatry, and Endocrinology continues its useful career in the volume for 1942, though we miss the admirable introductory summaries formerly given by the editor of each section. That on endocrinology has, however, an interesting note on Prof. Magnus-Levy, who, we are glad to learn, after 50 years' work in Germany has now found a safe haven at Yale, where he had his basal metabolic rate repeated at the age of 76, the first record having been made when he was 26. In that interval his energy output per hour had decreased by 17%—rather more than the predicted amount. In a discussion on the indications for termination of pregnancy for mental disorders the interesting conclusion emerges that the death rate for confusional states (generally associated with bodily strains) is 15 to 20%, but that survival nearly always means recovery, whereas schizophrenic patients rarely recover. In the agitated depressions associated with the menopause treatment with diethylstilboestrol was followed by recovery or marked improvement in 48%, which the editor considers rather a disappointing result—but surely it is an advance? This oestrogen, contrasted with hexoestrol and octofollin, shows a higher toxicity, though in suitable doses all three seem decidedly helpful in the menopausal syndrome. Octofollin, however, has no chemical relationship with the natural oestrogens and is relatively active by the mouth. The best point for interruption of the lateral spino-thalamic tract for relief of intractable pain is stated to be just below the trochlear nerve, because the fibres are most superficial in this part of their course. In the diagnosis of brain tumours great stress is laid on the occurrence of isolated convulsive seizures without signs of increased intracranial pressure. In an interesting discussion on aphasia it is stated that it is unwise to lateralize a lesion solely on its presence, and cases are quoted to support this opposition to the conventional Broca view. On more general psychiatric topics we may refer to the statistical evidence supporting the popular idea that the mobile mechanized type of warfare is less damaging to the mental balance than the static trench type.

The whole volume bears witness to active advance in the subjects dealt with despite the unfavourable conditions under which scientific work not directly connected with war is being carried out.

TREATMENT OF FRACTURES

Fractures and Fracture Treatment in Practice. By Kurt Colsen, M.D. (Pp. 147; illustrated. 12s. 6d.) Johannesburg: Witwatersrand University Press. 1942. Obtainable from the Press, Surgery Department, Medical School, Hospital Hill, Johannesburg.

Management of Fractures, Dislocations, and Sprains. By John Albert Key, B.S., M.D., and H. Earle Cornwell, M.D., F.A.C.S. Third edition. (Pp. 1,303; illustrated. 63s.) London: Henry Kimpton. 1942.

The author of the small book on *Fractures and Fracture Treatment in Practice* tells us that it is written for the use of students preparing themselves for qualifying examinations and of practitioners who need a brief review of the subject. It should serve these purposes admirably. Introduced by the professor of surgery at Johannesburg, who writes that Dr. Colsen has for a number of years now conducted the fracture tutorial class in the University of Witwatersrand, the book is a South African product which should export well. It is clearly written, not overloaded with detail, and well punctuated with simple line drawings which clearly depict what it is intended to illustrate. It consists of two parts: the first nine chapters comprise general considerations such as the forces responsible for fracturing bones, the healing of fractures, the general principles of treatment, complications, and pathological factors. The last eighteen chapters give descriptions of special fractures such as of the clavicle, those round the ankle, the face and jaws, ribs and sternum, etc. The book is essentially practical and not too matter-of-fact; thus we were pleased to read under Colles's

fracture that it was first described by Abraham Colles in 1814, and that the fractures at the ankle are historically associated with the names of Pott and Dupuytren. An index completes this excellent little manual.

The third edition of Key and Conwell's book is welcome if only because of the revision of the chapter on compound fractures which has been made necessary by the introduction of the sulphonamides or, as some of our American friends prefer to call them, "the sulfa drugs." This edition, however, includes other extensive changes, particularly in the sections allotted to fractures of the hip and spine and those of the arm and foot, while a new section on war injuries adds further to its value. The make-up is excellent, printing being clear and the illustrations, particularly the reproductions of radiographs, good. The style of the text makes for easy reading and sustains interest. There are many wise comments such as Osgood's statement (p. 342) that "the key that opens the door of diagnosis is suspicion," and (p. 433) "the frequency with which lesions of the intervertebral disk are suspected and found will vary directly with the interest of the examining physician." The discussion of laminectomy in spinal injuries is well balanced, as is also that on another thorny question—operation for suspected dislocation of intervertebral disks. Few will disagree with the conclusion that "patients with low back pain and sciatica should not be subjected to spinograms and intraspinal operations until conservative treatment has failed to relieve their symptoms." Some older surgeons, remembering experiences of the last war, will be interested to read in the section on war surgery that non-irritating vitallium and stainless steel and the sulphonamide drugs have made it possible to use internal fixation in compound fractures with relative safety. For direct implantation in wounds the authors advise a mixture of sulphathiazole and sulphanilamide. This book is full of information and little fault can be found with any of it. The chapter on fractures of the skull and brain injuries is essentially sound and in line with the high standard of the rest of it. It should be more than ever appreciated now that traumatic lesions are so much in front of us. We have the highest praise for it and can thoroughly commend it to surgeons and practitioners everywhere.

MICROBIOLOGY OF CANNED FOODS

Canned Foods: An Introduction to their Microbiology. By J. G. Baumgartner. (Pp. 157; illustrated. 10s. 6d.) London: J. and A. Churchill, 1943.

For many years the popularity of canned foods in this country has been growing, and now in wartime they have become of national importance. Though a great deal of valuable research work has been carried out by the National Canners' Association in the United States and by the Food Manufacturers' Research Association and other bodies in Great Britain, it still remains true that, owing to the numerous variables concerned, control is not always perfect and wastage occurs, sometimes on a relatively large scale. Dr. J. G. Baumgartner, therefore, need make no apology for the admirable little book he has written on the subject of canned foods. As chief bacteriologist to Messrs. Crosse and Blackwell he has had an admirable opportunity of acquainting himself with modern canning practice. The results of his experience and of his wide reading are set down in a series of well-balanced comprehensive chapters dealing with the microbiological aspect of canning in its widest sense. A short introductory chapter on the general properties of bacteria, moulds, and yeasts is followed by a description of the various methods in current practice for controlling spoilage in canned foods. The technique of processing, which differs, of course, according to the type of food in question, together with the principles on which it rests, is dealt with at some length. There is a most informative chapter on the types of microbial spoilage that may be met with resulting from such factors as bacterial growth in the food before processing, under-processing, or infection through leaking seams during cooling. The effect on the cans of faulty technique in processing, such as may follow over-filling, incorrect retort operation, or under-exhausting, is also described. Laboratory workers will derive much benefit from the chapters on the examination of canned foods and of can seams. The book will be of interest and help to medical officers of health,

sanitary inspectors, and to public health and industrial bacteriologists. It is packed with useful information and will be found worthy of being placed alongside volumes having far more pretentious exterior.

Notes on Books

After its first appearance in 1936 Dr. E. NOBLE CHAMBERLAIN'S *Symptoms and Signs in Clinical Medicine* went through a second edition and three reprintings in the course of five years. Now the third edition is published at 30s. by John Wright and Sons, Bristol, to whose courage and enterprise in overcoming difficulties after repeated destruction of their works, the author pays tribute in his preface. The book remains a very useful introduction to medical diagnosis which should appeal especially to the more advanced student. Its essential clinical character has been carefully preserved but some additional laboratory and scientific investigations are included. There is a chapter on radiology by Dr. P. H. Whital and Dr. Norman Capon has again revised his valuable chapter on the examination of sick children. Dr. Noble Chamberlain acknowledges also his debt to a number of other colleagues for constructive criticism and help in revising various sections. Throughout the book there is evidence of careful sifting of data and correction or rearrangement where necessary. The many and well-chosen illustrations are again worthy of praise.

Wise Eating in Wartime is the title of a booklet prepared for the Ministry of Food by the Ministry of Information (H.M. Stationery Office: 4d.). It consists of fifteen broadcast talks for adults by Dr. CHARLES HILL on what to eat and what to avoid, the aim being to underline those dietetic items which give the maximum amount of nourishment. Dr. Hill spoke regularly on the B.B.C. "Kitch Front" programmes, and two of his earlier series of talks have been published on behalf of the Ministry of Food: *Your Bal Food in Wartime* and *Wartime Food for Growing Children*. This pamphlet completes the circle. By common consent Dr. Hill is master of the art of homely talk over the radio. He makes every point tell, and never forgets that the bulk of his listeners are simple folk who are willing to learn but hate patronage or pomposity; like instruction to be given in words they themselves use, with plentiful spicing of their own kind of humour. The printed version has the authentic ring.

The Ling Physical Education Association (Hamilton House, Bidborough Street, W.C.1) has published a pamphlet (price 2s.) *The Use of Exercise in the Post-War Rehabilitation of Children Occupied Countries*. It was written, at the request of the International Women's Service Groups in Great Britain and of organizations which are training volunteers for various branches of relief work in the occupied countries after the war, by two medical women primarily concerned with children's welfare (Dr. Ol Rendel and Dr. Ursula Shelley), and two specialists in physical education (Miss Mary Lace and Miss Bronwen Lloyd-Williams) who are also members of the Chartered Society of Massage and Medical Gymnastics. One of the contributors had experienced the condition of children in Russia during the last war, and another during the Spanish civil war. The pamphlet has been submitted to authorities with knowledge of relief work abroad, and all have agreed that there is need for advice on the subject, because too much stress cannot be laid on the value of exercises, games, and entertainment for these children when they are released from the enemy's grip and properly nourished. Starving children must first be fed. Next they must be restored to health by every means in human power. Rest and relaxation and well-planned physical education can help in this.

The Medical Officer to the Midlothian Battalion, Home Guard, has written a small, pocket-size booklet entitled *You and Your Comrades*, which gives in 31 pages practical hints on first-aid treatment. The author has borne in mind the special circumstances likely to apply if and when the Home Guard goes into action. The "first field dressing," he says, must always be carried in the special pocket for it at the top of the right trouser leg. This consists of two separate gauze pads attached to 2½ yards of bandage, each wrapped in a white waxed cloth cover. Instructions are given for its use, and also on the treatment of shock, haemorrhage, fracture, wounds, and unconsciousness. Extreme caution is urged in assuming that a man is actually dead. "His breathing and pulse may have stopped and he may be lying limp and inert, and yet often it may happen that life can be restored." Company commanders are advised to provide for two medical orderlies and eight stretcher-bearers for every 100 men, as there is scant chance at the moment of a medical officer being in the field. The booklet is published by E. & S. Livingstone, 16, Teviot Place, Edinburgh, at 4d. a copy.

THE NUTRITIONAL STATE OF STAFF IN A LONDON SECTOR HOSPITAL

BY

HELEN PAYLING WRIGHT

WITH THE TECHNICAL ASSISTANCE OF

J. L. HOSKINS

The following observations upon the nutrition of 22 probationer nurses at a large London teaching hospital evacuated to the country may be of interest. They were made during the first three months of 1943, a time of year at which green vegetables are scarce and fresh fruit unobtainable. The subjects took all their meals in the institution, having no additions to their diet except occasional buns and sweets. The findings on a small group of laboratory staff at the same hospital who received home-prepared diets with full civilian rations are included for comparison. The results for the two groups are given in the following table:

		Vitamin C Excretion in mg.			Urea g. per 24 hrs.	Serum Protein %	R.B.C. in Mills.	Hb%
		Initial Level	After 250 mg. Once	After 250 mg. Daily				
Nurses	Means Coeff. of variation...	13	26	88	17	6.6	4.85	88
		34	106	56	23	9	7	9
Laboratory staff	Means Coeff. of variation...	21	83	141	26	6.8	5.16	102
		13	51	61	20	6	1	3

Blood Findings.—In no instance was the red cell count below the lower limit of normality for women (4.28 mills., Price-Jones *et al.*, 1931). The haemoglobin, determined by the faldane method with apparatus conforming to the B.S.I. standard, gave an average of 88%, which falls below the lower limit of normality (90%, Price-Jones *et al.*), and much below the mean for healthy women of comparable ages (98%). The present findings correspond closely with those of Wills and her colleagues (1942) for a similar group of nurses. Although the degree of anaemia was never gross it might have accounted for the greater sense of fatigue experienced by the more anaemic subjects. It also showed that their iron intake was probably insufficient for this group of young women. The blood findings for the second group were more satisfactory, even allowing for the fact that five of the six subjects were men, and no sign of iron deficiency was present in any of them.

Vitamin C.—Excretion of this vitamin was determined by the method of Harris and Ray (1935). The urine passed during a period of 24 hours was tested as follows. The volume of each voidance was measured, and a 10 c.cm. sample transferred to a bottle containing 2 c.cm. of glacial acetic acid. These samples were collected four times daily, so that estimates could be carried out promptly. The vitamin C excretion was determined on three occasions for each subject: (i) on customary diet; (ii) after one dose of 500 mg. of ascorbic acid given 8 hours previously; (iii) after 250 mg. taken daily for seven days. The initial figures showed that the vitamin C level of all the subjects was low (see Harris and Ray, 1935), though none complained of any symptoms ascribable to this deficiency. After one large dose of ascorbic acid the average excretion rose to within normal limits. The rise in the average was, however, deceptive, as can be seen from the large coefficient of variation; a few subjects responded markedly, while 11 failed to improve appreciably. After treatment for seven days a satisfactory level was reached by all except one, who possibly failed to take the tablets regularly. It may therefore be concluded that the diet taken by these nurses was deficient in vitamin C. Several of them volunteered the statement that they felt better and "more alive" after receiving the ascorbic acid for a week. The results for the group of laboratory workers showed a consistently better rate of excretion. Initially all fell within the lower limit of normality, and after the ascorbic acid supplements their excretion rate rose higher than that of the other group. This shows that their original diets contained a larger amount of this substance.

Urea Excretion.—The estimations of urinary urea were performed on 24-hour samples as a guide to the protein content

of the diets. Calculated on the assumption that urea excretion $\times 2.9$ = protein intake, and neglecting the small loss of nitrogen in the stools, etc., it appears that this group of nurses were receiving about 50 g. of protein daily. This is probably too low an intake (see Gaunt, 1943), especially as a considerable proportion was of vegetable origin and consequently low in certain essential amino-acids. The urea excretion for the second group was considerably higher, the calculated daily protein consumption being 76 g., which should be adequate even though low in animal proteins.

Serum Proteins.—These were estimated by a nesslerization method. In one nurse only (in whom it was 5.8 g. %) was the serum protein below the lower limit of normality. The relatively high level of serum proteins was not unexpected, for with low-protein diets but without starvation they appear to be sustained at the expense of other body proteins.

MEDICAL SICKNESS AND LIFE ASSURANCE

The annual meeting of the Medical Sickness, Annuity and Life Assurance Society, Ltd., was held on June 23, Mr. R. J. McNeill Love, F.R.C.S., Chairman of Directors, presiding.

The Chairman said that the new business in the Life Assurance Fund had increased from £141,188 to £267,303, and the total of this Fund now stood at over one and a half millions. All policies for life assurance effected since the outbreak of war bore an exclusion agreed upon by the Life Offices Association that in claims directly or indirectly due to the war the sum assured should not be paid, but the premiums should be returned. The words "indirectly due to war," however, had opened up such a wide field of conjecture and discussion that the directors of the Society had decided in principle that claims directly due to enemy action should follow the exclusion, but that all other claims should be paid in full so far as the funds of the Society allowed.

In the Sickness Fund the premiums were slightly higher, and the year having been moderately healthy, there was only a very slight increase in claims. The funds of the Society had increased by £222,921, and now stood at £2,578,239, which was one and a half millions more than at the time of the Society's jubilee in 1934. The holding in British Government securities, which represented 36% of the total investments, had increased during the year to £955,904. All new money and redemptions were invested in 3% Savings Bonds.

In a reference to the important discussions now taking place on the Beveridge Report, the Chairman said that the proposed abolition of private practice as at present carried out, and the transformation of doctors from the complete freedom they had always enjoyed to the restricted activities of salaried civil servants, opened up a startling prospect. What was to happen to the capital of thousands of doctors which had been invested in the purchase of a practice or a share in a partnership? Members might be assured that the Board was closely following the discussions now taking place so far as the interests of its members were concerned. He ended with an appreciation of the services of the manager and secretary, Mr. Bertram Sutton, and staff.

At a recent meeting of the Association of Industrial Medical Officers Mr. J. L. Smyth, whose work has brought him into contact with industrial doctors, spoke on the education of the industrial medical officer. He said that the doctor in industry must bring to his work a wide knowledge of people, of processes, and of the substances used in various industries, a knowledge which ought to be acquired before he began his work in the factory. It was the doctor's province to see that the human machinery was properly cared for. He should spend time in the works rather than wait for patients to come to him. It was his duty to interpret and bring to the notice of the management the latest results of research in industrial hygiene. A works doctor should not hold the position of referee for the local county court. Dr. Frank Gray spoke on the co-operation between the general practitioner and the industrial medical officer. He said it was important that continuity of treatment should be secured. Industrial medical officers had special knowledge of factory conditions and their effects on health and of the patient as a factory worker, while the general practitioner understood the patient's home circumstances, his family, his diet, his clothing, and, even in wartime, the conditions of life of more than half his day. The Ethical Rules for Industrial Medical Officers drawn up by the B.M.A. were an excellent basis for the co-operation between the two. It was intended that the letter of these rules should not be too rigidly adhered to; it was the spirit behind them that mattered.

HOSPITAL MEALS

A conference on hospital meals, arranged by the Food Education Society, attracted a gathering which packed the theatre of the London School of Hygiene and Tropical Medicine. Mr. ERNEST BROWN, Minister of Health, who presided, said that every hospital of over 100 beds ought to employ a dietitian. When such a person was employed there was a notable improvement in both the nutritive value and the tastiness of meals. He had arranged with the Minister of Labour and National Service that students taking a diploma in dietetics should not be called up until the end of their training. Officers of the Ministry, knowledgeable in kitchen management, continually visited E.M.S. hospitals, and the response of these institutions to his exhortations had been gratifying. Further, there was hardly a hospital which had not since the outbreak of war appreciably reduced the amount of edible food wasted. One hospital during a recent three months had increased its potato consumption by 40% and decreased its bread consumption by 20%.

Lord HORDER, president of the society, said that in this country we were by no means behind Europe and America in dietetics. With the attention now paid in communal restaurants and factory and school canteens to variety and attractiveness in food it would be an anomaly if it were found in any large hospitals that very little had been done to vary the monotony of the meals. But there was always scope for the exercise of more imagination and for new techniques in preparation and service. Sir ALFRED WEBB-JOHNSON, P.R.C.S., said that dietitians should have control not only of their own special kitchens but of the general hospital kitchen as well. It was quite possible to reconcile needs, tastes, and provision, but the problem of food was in some ways more difficult than it had been to an earlier generation, which had a plentiful supply of natural foods. The place of these had to some extent been taken by artificial preparations, the manufacturers of which, to make them attractive, had in some cases deprived them of vital constituents.

Navy and Army Rations

Surg. Vice-Adml. Sir SHELDON DUDLEY, M.D.G. of the Navy, spoke on the sailor's diet in general. The one-time invariable meal of roast beef and plum duff had now given place to a more varied menu. He believed that the sailor's dislike of greenstuff was due to overfeeding in the naval training establishments. In the naval hospitals there were expert dietitians for special diets—eggs, chicken, and fish. No doubt a good many substitutes had now to be used, but care was taken that cooks were well trained and able to select their dishes and garnish them attractively. The Navy did not prove of synthetic vitamins in hospital diets, and the necessary supplements were made with black-currant purée and the like. Special cupboards and trolleys kept the food hot, and continual supervision of the kitchen ensured that it was not over-cooked. He made some civilian mouths water by giving the menu in naval establishments for that particular day: Breakfast: porridge, haddock; dinner: liver and bacon, potato and cabbage, ginger pudding, sauce; tea: bread-and-butter and jam; supper: meat roll, sauce, potatoes. In addition: 1/2 lb. bread, 1 oz. butter (not margarine), 1 1/2 oz. sugar (plus 1/2 oz. to the galley for cooking), 1/2 pint milk, and 2/7 oz. tea.

Lieut.-Gen. Sir ALEXANDER HOOD, D.G.A.M.S., said that the soldier when he went into hospital did not as a rule suffer much impairment of appetite. As an example of the variety of rations issued in the Army with its troops from many quarters of the world he mentioned that in the Middle East the rations were of 35 different types. British soldiers were conservative in their eating habits: it took them a long time to get accustomed to salads, but a few years ago in the Sudan he found a regiment enjoying omelettes and salads at midday and reserving their heavy meal for the evening. Local resources in the Western Desert were not plentiful, but no Army in the history of war had been better fed than the Eighth, and he had never seen a finer-looking set of men. There were four basic types of diet in hospital: ordinary, milk, chicken, and fish; but every hospital carried large supplies of extras such as jellies, powdered soups, and dried vegetables,

and from these there were very few diets that Army cec could not turn out reasonably well. It was only those who had been in West Africa, where potatoes would not grow who knew how the men looked forward to dehydrated vegetables which, thanks to their nutritionists, were being sent out.

Dietetic Deficiencies

Dr. GEORGE GRAHAM said that during the war he had seen six cases of scurvy, one of them in a soldier. But the people who got scurvy nowadays were usually either old men who did their own cooking or women who lived on freak diets. Vegetables were often not looked at because badly cooked but there had been a change in this respect during the war. It might be said that if vegetables looked nice when served they were probably nutritious also. Another thing that had been learned was that cabbages, lettuce, and the like which had been cut for any length of time tended to lose vitamin C. Hospital food should be taken to the laboratory periodical and if there was vitamin deficiency the kitchen arrangements should be investigated. Sir BERNARD DOCKER, president of the British Hospitals Association, considered that, taken as a whole, the charge of poor feeding levelled against hospitals could no longer be sustained. Where a patient required a special diet which was the subject of a medical prescription it was necessary only for the doctor's orders to be observed but in many cases the doctor ordered only a "light diet" and this made it necessary for somebody to use discretion. He also referred to nurses' diet and the recommendation of the Rushcliffe Committee on the desirability of hospital housekeepers, whether nurses or not, being properly trained in dietetics.

Finally, Dr. W. A. LETHBRIDGE of the Ministry of Health referred to the booklet *War-time Feeding in Hospitals*, published by the Ministry, and described the close collaboration of the Department with the hospital authorities on this matter of meals. The Ministry did not encourage the general consumption of synthetic vitamins by people who were or should be in a position to obtain a properly balanced diet.

BEIT MEMORIAL FELLOWSHIPS

The Trustees of the Beit Memorial Fellowships for Medical Research, in their report for 1942-3, note with pleasure the election this year again, as in 1942, of 3 past Fellows to the Fellowship of the Royal Society—namely, I. de Burgh Da Silva (Fellow, 1920-3), W. G. Penfield (1921), and S. Zuckerkandl (1934-7). Out of the 25 present Fellows there are now 15 seconded for whole-time war work.

The following elections have been made, with permission for each Fellow to be seconded at any time for war duties:

4th Year Fellowships (£500 a year).—J. J. D. King, L.D.S., Ph.D., to continue his studies of dental caries and periodontal disease, at the Nutrition Laboratory of the Medical Research Council, London, N.W. P. C. Williams, B.Sc., to continue his studies of natural and synthetic oestrogens, at the Courtauld Institute of Biochemistry, Middlesex Hospital, London University.
Junior Fellowships (£400 a year).—Margery E. M. Cutting, B.Sc., to study the physiological metabolism of organs in infancy, at the Department of Medicine, Cambridge University. A. Kleczkowski, M.D., Ph.D., to study serological reactions in reference to size and shape of antigen and antibody particles, at the Rothamsted Experimental Station, Hertfordshire. G. J. Poplar, M.D., for experimental study of fatty and degenerative changes in the kidney at St. Thomas's Hospital Medical School, London University. Ethel G. Teet, B.Sc., Ph.D., to study the chemical structure of Gram-positive and negative micro-organisms and to develop antibacterial agents, at the Department of Chemistry, Birmingham University.

HOME SERVICE AMBULANCES

"Even in the middle of war, when all else is subservient to the demands of the Services . . . the needs of the ordinary civilian invalid must be met." This is the opening note of the annual report of the Home Service Ambulance Committee of the Joint Council of the Order of St. John and the British Red Cross Society, and then shows how this work has been done. During the twelve months ended Dec. 31, 1942, patients carried numbered 248,689, bringing the total since the start of the service to 2,875,794. The total number of ambulance stations equipped by the committee is 132, and there are 379 affiliated stations. The linking up of ambulance stations throughout the country had very great advantages before the war but these have become more marked with the need for strict economy in the use of man-power, petrol, and transport generally. The committee has continued the arrangement made with the Ministry of Health at the beginning of the war providing mobile x-ray facilities through E.M.S. hospitals in the Greater London area. A twin-unit technique has been developed for orthopaedic work under operating theatre conditions.

THE GOVERNMENT'S MILK POLICY

he rationalization of retail distribution of milk, though resulting in economies in transport and man-power, has in itself created a problem which touches public health very closely. Consumers who previously bought pasteurized milk may now be compelled to accept raw milk, and those who sought to protect their children against tuberculosis of bovine origin by buying tuberculin-tested milk may now be supplied with ungraded milk. Having in the national interest deprived the consumers of their freedom of choice of milk vendor, the Government now feels obliged to ensure that in those areas in which rationalization has been introduced some control at least should be exercised over the quality of the milk supplied. In the White Paper on Milk Policy recently issued the Government proposes to schedule areas in which it will be an offence to sell milk retail unless it is (1) heat-treated as defined by Order, (2) lawfully sold as T.T. milk, or (3) "accredited milk" sold by a retailer who sells the milk from a single accredited herd. The number and size of the areas to be scheduled will presumably depend to a large extent on the availability of pasteurizing plant. In areas of population exceeding 10,000, dairymen are being encouraged to make plans for organizing the heat treatment of milk. Where satisfactory arrangements cannot be made by the trade itself, local authorities will be enabled to install and operate pasteurizing plant. As was advocated in this *Journal* many years ago, the policy is to be adopted of transferring to the Ministry of Agriculture and Fisheries the functions of local authorities relating to the conditions under which milk is produced on the farm. Responsibility for the protection of milk against infection and contamination during transport and distribution will remain with local authorities. This means, in effect, that the agricultural authorities will supervise the production, and sanitary authorities the distribution, of milk. Further, the Government proposes to stimulate the T.T. milk industry by paying a premium of 4d. a gallon direct to the producer and allowing for T.T. milk to be sold to the public at a price only slightly in excess of that for ordinary milk.

Taken together, these proposals constitute a step in advance, though only a small one. They clearly represent a compromise between the Ministry of Health, the Ministry of Food, the Ministry of Agriculture and Fisheries, the National Farmers' Union, and the Milk Marketing Board. The establishment of scheduled areas in which, apart from certain classes of raw milk, only heat-treated milk may be sold, is of importance in showing that, within limits, the Government approves the principle of compulsory pasteurization. Though many medical men are of the opinion that T.T. milk should be pasteurized in order to render it free from the risk of carrying other diseases than tuberculosis, few will grumble at its being permitted to be sold raw in scheduled areas. What everyone, however, who understands the present system of milk designations will regret is that "accredited milk" should be classed along with heat-treated and T.T. milk. Accredited milk is produced under conditions that do not ensure its safety for the consumer, even in respect of tuberculosis. The animals in the herd are submitted to clinical inspection by a veterinary surgeon four times a

year; but, as experience has shown, the veterinary inspector can no more diagnose early tuberculosis of the udder by palpation than a doctor can diagnose early tuberculosis of the lung by auscultation. Bacteriological examination of the milk is as necessary for the one as radiological examination is necessary for the other. But bacteriological examination of accredited milk is restricted to tests for cleanliness; there are no tests for tuberculosis. It is therefore not surprising that, judged by the examination of milk coming into London in 1937, accredited milk is found to contain tubercle bacilli almost as often as ungraded milk. The term "accredited" is a misnomer and conveys to the general public a suggestion of safety which the milk that bears the name is far from possessing. Dr. Esther Carling has performed a public service in pointing this out in her letter to the *Times* of July 19. If the Government cannot be induced to withdraw accredited milk from the list of those to be sold in scheduled areas—and presumably opposition from the farmers will prevent it from doing so—pressure should at least be brought to bear on it to enable local authorities to stop the sale of any milk found to be infected with tubercle bacilli until the offending animal or animals have been removed from the herd. Anomalous though it may seem, tuberculous meat, which would normally be cooked, can be condemned under present sanitary law, whereas tuberculous milk, which is often consumed raw, cannot. If arrangements were made for accredited milk found to contain tubercle bacilli to be temporarily diverted to a pasteurizing plant, then some at least of the damage that it might cause would be avoided. This should not be difficult, because the Government expressly states that there will be no added cost to the producer-retailer in submitting his milk to heat treatment; and that by so doing he will run no risk of losing his customers to larger organizations, as all customers are registered with particular suppliers and no change is possible without the approval of the Ministry of Food. Incidentally, the effect of stopping infected accredited milk from being sold would probably be to encourage producers to go in for T.T. milk or for pasteurization. If raw accredited milk is undesirable for the general public in scheduled areas, it is equally undesirable for school children. Yet the White Paper states that every effort will be made to provide all schools with heat-treated milk, T.T. milk, or milk exclusively from single accredited herds. Again, this last class of milk should be withdrawn. If neither heat-treated nor T.T. milk is available, then the children should be provided with dried milk, preferably flavoured with chocolate.

To most readers of this *Journal* the Government's policy will prove disappointing. It must be remembered, however, that public opinion on the milk problem in this country still remains unstirred. We have grown so accustomed to milk of poor keeping quality, to milk that is often infected with tubercle or *abortus* bacilli, to milk that from time to time becomes adventitiously contaminated with pathogenic organisms of human or other origin, that figures of milk-borne disease no longer have the power to move us. When we think of what milk could be like, and then realize what it is like, we cannot help but be appalled by the extent of popular apathy. Is it surprising that the troops coming from the United States, where so much has been done to furnish a clean, safe milk to the human population, are not allowed to be provided officially with liquid milk in this country? Until we ourselves can look at our milk supply as the Americans look at it, until we educate the public to demand safe milk and to go on demanding it, and until we insist that the health policy of this country shall be dictated by doctors and not by farmers, can we blame the Government if its forward step in milk legislation is but the step of a timid, halting child?

HEALTH AND SOCIAL MEDICINE

A few weeks ago the argument was advanced in these columns that before external authority makes any attempt to regiment or even to reorganize our profession the people of this country should be guaranteed the basic necessities of life in terms of food, housing, clothing, and recreation in return for honest work, with the safeguard against interruption of income which lies at the root of the Beveridge plan. The fact that poverty and bad environment undermine health of body and mind is so widely acknowledged as to be a commonplace of social philosophy. What lacks equal recognition by many who have an itch to construct health programmes is the need for a long-term policy to protect the individual and the community against forces that hamper the full development and maintenance of man's mental and physical capacity. Such a policy was outlined last year by Sir Farquhar Buzzard in a paper on the place of social medicine in the reorganization of health services.¹ Its chief aim, he held, would be to expose the sources and bases whence arise ill-health and disability by investigating the social, genetic, environmental, and domestic factors that affect the incidence of human disease. A second and equally important aim would be to search for and promote protective measures other than those usually employed in remedial medicine. Sir Farquhar argued that the first step forward to the goal was the setting up of professorial departments or institutions of social medicine in close association with hospitals and having a fourfold purpose: (1) To foster research; (2) to reorientate the aims of the medical curriculum in such a direction that the doctor of the future will be trained not only to fight disease but to be an architect of personal and public health; (3) to organize postgraduate training in social medicine; (4) to co-ordinate and guide the activities of social and health services already established or to be established in the future. Hard on the heels of that pronouncement came news that the University of Oxford, with moral and financial support from the Nuffield Provincial Hospitals Trust, had resolved to establish an institute and professorship of social medicine, whose purpose would follow closely the lines indicated by the Regius Professor of Medicine. Action followed decision, and the first holder of the chair, Prof. John A. Ryle, is already working in Oxford at the nascent Institute of Social Medicine.

Recent letters to the *Times* by the two men most closely concerned with Oxford's new departure have brought its aims before a wide public and related them to a topic of the day—that is, to a comprehensive health service according to the Beveridge report. Sir Farquhar Buzzard, writing in the *Times* of July 21, invited attention to broader considerations than such controversial topics as salaried medical service, free choice of doctors, the preservation of the voluntary hospitals system, and changes in the constitution and areas of local government. He recalled that the aim of a comprehensive health service, according to Sir William Beveridge, is to produce and maintain a nation so healthy that it is capable of maximum production, thereby becoming both prosperous and contented. An obstacle now interfering with that objective is the fact that there are not nearly enough doctors to carry out the threefold duties of promoting health, of preventing disease, and of

curing the sick. Doctors, Sir Farquhar says, "simply have not the time necessary to do their job with satisfaction either to the community or to themselves. There are too obvious methods of dealing with this difficulty. The number of doctors must be increased, or their work decreased. The first alternative is a melancholy and defeatist policy the second deserves more careful investigation than it has yet received." It is indeed true that the doctor's time is mostly taken up with minor disorders of health, physical and mental, which though disabling are preventable. No less true is it that their origins are plain for those who have eyes to see. "Staring us in the face is a low and inadequate standard of living caused by bad housing, imperfect supply of air, light, space, and water, ignorance regarding hygiene, food, and drink, evasion of the problem presented by sex and heredity, lack of leisure and recreation, and last, but by no means least, the prevalence of dirt and dirty habits. Turning to the mental side, equally obvious are lack of social security and all the nervous strains and anxieties directly due to this and to the physical and environmental factors already mentioned." The question thus clearly posed is whether to attack the sources of ill-health or to continue indefinitely content with treatment and rehabilitating the unhealthy. Developing his plea for joint and co-ordinated efforts in preventive and social medicine, Sir Farquhar pointed out that the training and qualifying of the requisite number of doctors to deal adequately with the present ill-health of the nation would take ten to twenty years at least; but meanwhile the volume of ill-health might be so greatly reduced by improvement of social conditions that the larger number of doctors might well be superfluous. He ended with these significant words: "We should welcome an improved and comprehensive health service, but only if associated with the pledge to the Government to eradicate as far as is possible the most obvious causes of ill-health."

Prof. John Ryle's letter in the *Times* of July 24 was written to supplement Sir Farquhar Buzzard's advice from the point of view of one whose ideas are in close accord with his. "The majority of doctors have been compelled to the belief that their first function is the treatment of disease or injury and not the maintenance of, or education for, health. Medical students are still largely bred in that belief; they learn little of the foundations, meaning, and measurement of health, and rarely examine a healthy subject. The public for the most part think of the doctor as someone to consult in times of sickness only." Acknowledging the wonderful achievements of the environmental health services, Prof. Ryle had to note that latterly even these preventive services have been compelled by the great mass of our infirmities to take over more and more of the treatment of developed disease, and except in four or five directions they still have relatively small powers for contributing to constructive programmes of social medicine in hygiene. "If examination for health and if training, feeding, housing, and education for health in the armed Forces in wartime are necessary for national defence and survival, surely they must come to be regarded as equally necessary for national efficiency and survival in time of peace. Employer and employee, equally with the High Command and the rank and file, must learn the mutual benefits which can accrue from that health or 'wholeness' (in a bodily, mental, and moral regard) which is a possible goal, and must in time become our first economy." And so the two letters from Oxford converge to the point with which we began, and reinforce our view by weighty reasoning.

DEATH OF THE PRESIDENT

Members of the British Medical Association will learn with deep regret that our President, Sir Beckwith Whitehouse, M.S., F.R.C.S., after attending the meeting of Council at 3.M.A. House on July 28, had a heart attack when beginning his journey home and died soon afterwards in University College Hospital, London. Sir Beckwith, who was in his 61st year, had had a most distinguished career and was professor of midwifery and diseases of women in the University of Birmingham, and gynaecological surgeon to the General and Queen Elizabeth Hospitals, Birmingham. He was an Honorary Member of the Canadian Medical Association and an Honorary Fellow of the American College of Surgeons. He joined the British Medical Association soon after graduation and was honorary secretary, vice-president, and (in 1936) president of the Section of Obstetrics and Gynaecology. The Birmingham Branch made him its president for 1934-5. At the Aberdeen Meeting of the B.M.A. in 1939 Sir Beckwith Whitehouse was appointed President-elect, and but for the war he would have presided over the Association at Birmingham in 1940. He succeeded Dr. Thomas Fraser in the presidential chair in 1942, and the Council at its recent meeting unanimously and with acclamation resolved to recommend to the Representative Body his re-election for the year 1943-4. On behalf of all our fellow members we offer sympathy to Lady Whitehouse and her children in their sudden bereavement. A memoir, with portrait, will appear in next week's *Journal*.

THE NATURE OF INFLUENZA VIRUS

The question of size has always assumed great importance in discussions on the nature of viruses. Larger members like the viruses of vaccinia and psittacosis are almost universally accepted as small living parasites, akin to the bacteria, and their sizes present no obstacle to a structural complexity sufficient for their metabolic activities and adaptative mutations. Indeed, Rivers and his co-workers have shown that the elementary bodies of vaccinia contain, in addition to protein, fat, carbohydrate, and copper, a growth-promoting factor which is probably biotin, and there is good evidence that they multiply like the bacteria by simple binary fission.

Until recently influenza virus was generally considered to belong to this large-size group, its particle diameter being accepted as approximately 100 m μ . Recent papers by Chambers *et al.*,¹ however, present convincing evidence that the virus unit has a diameter of only about 10 m μ and a molecular weight of less than 1,000,000: this would place it among the very smallest of the known viruses, the sizes of which are comparable with large protein molecules. Moreover, their preliminary studies have indicated that the virus protein is no more complicated, chemically, than the infectious agent of tobacco mosaic, which Stanley² showed could be isolated in paracrystalline form. Since Stanley's pioneer work many plant viruses have been crystallized as true three-dimensional crystals, and there is now little doubt that they are chemically pure protein substances. But so long as the animal viruses resist all attempts to obtain them in crystalline form it is perhaps legitimate to consider them of fundamentally different nature from the plant viruses. It may be significant, however, that the infective agent of poliomyelitis, with an estimated particle diameter of about 12 m μ , is considered by some workers to be a non-living protein which can be repeatedly precipi-

tated without loss of infectivity. Whether influenza virus belongs to this group of infectious chemical agents remains to be determined: it is certainly difficult to imagine a chemical substance possessing its powers of adaptation and its antigenic mutability.

One of the greatest mysteries in the epidemiology of influenza is the mechanism whereby the virus survives through long interepidemic periods. Andrewes³ postulated a basic non-pathogenic virus, harboured by normal human carriers, which might under favourable conditions evolve through several grades of increasing antigenic complexity and pathogenicity. Recent work by Shope⁴ on swine influenza points to another interesting possibility. His experiments indicate that the lung worms which commonly infest pigs serve as an intermediate host for the virus, not only while they remain in the pig's lungs but throughout the excretion of their ova and their development through larval stages in the earthworm. The ingestion of earthworms by swine completes the cycle. As earthworms may remain infective up to 32 months, survival of virus from one epidemic to another becomes readily understandable. The most interesting feature of Shope's work, however, is the demonstration that virus, while in the lung worm, whether adult in the pig or larval in the earthworm, exists in a masked form; it is totally non-infective until awakened to activity by some provoking stimulus. Shope thinks that the onset of a swine epizootic is determined, not by the acquisition of the causative virus, but by meteorological or physical conditions which favour virus activation. Although a similar mechanism in human beings seems unlikely, it would be unwise to ignore the possibility. Human epidemics, like swine epizootics, usually occur during a particular season of the year, and epidemic foci often arise simultaneously and apparently independently, suggesting some activation of previously acquired infection rather than direct case-to-case transmission. Much further knowledge of the epidemiology of the disease as well as of the chemical and physical properties of the causative agent is required for a fuller understanding of the nature of influenza virus.

PLANT HORMONES

The concept that specific chemical substances secreted in small amounts by certain organs in the body exercise a profound influence on the growth and shape of the animal form has provided a fascinating chapter in the book of human knowledge. In the last ten or fifteen years, however, an equally fascinating supplement to that chapter has been written, for the growth and form of plants have also been shown to be controlled by specific chemical substances. These plant "hormones" are known as "auxins" (from a Greek word meaning "to grow"), and of them Went and Thimann⁵ have stated "that the auxins play a protean role in the development of plants, and influence a large number of processes both normal and pathological." Though the occurrence of plant hormones has only been securely established in the last ten years or so, Boysen-Jensen⁶ as long ago as 1910 found that, if he cut the tips off *Avena* (oat) coleoptiles and stuck them on again with gelatin and then illuminated only the tips, the tip and the base of the coleoptile curved towards the light. Thus under the influence of light a substance was being produced in the tip which was capable of diffusing through the rest of the coleoptile. This diffusible substance was

obtained from coleoptile tips by Went⁹ in 1926 and 1928. The chemical investigation of this substance was later carried out by Kögl and his collaborators in the years following its isolation by Went. A number of growth-inducing substances have since been obtained from plants. They have all been described as auxins. Eventually all auxins were classified as either auxin "a" or auxin "b." The first was given the chemical name of auxin triolic acid, and the latter was called auxenolonic acid. They both consist essentially of a 5-carbon ring including a double bond and carrying two or three side chains. In 1934 Kögl¹¹ isolated indole-3-acetic acid (hetero-auxin) from urine, and it was found to have a strong growth-stimulating effect in plants. Since then many related chemical substances—naphthalene acetic acid, indole butyric acid, etc.—have been found to have a growth-stimulating function in plants. It is noteworthy, however, that they stimulate growth by causing cell elongation, not cell division. This group of substances is particularly active in stimulating root growth. Mixed with lanolin and rubbed on to a plant they will cause roots to grow on the leaves or stem of a plant or even on the petals of a flower. Such substances are obviously of great value in persuading recalcitrant cuttings to "strike"—e.g., those of the yew, holly, and lemon. Spraying the unpollinated flowers of various fruits with some of these substances causes the fruits to develop without seeds. Seedless tomatoes have been one of the interesting and palatable results of these experiments.

One of the most surprising things about the auxins is their wide occurrence in animal tissues. They are present also in the excretions of the body—in saliva and urine. In the latter there is so much present that human urine has been used for the extraction of pure auxins. Since auxin is a growth-promoting substance it is not surprising that attempts were made to see if it was present in tumours. Extracts of mouse carcinomata, however, proved to be negative. It was observed to have no effect on the growth of tissue cultures, but embryonic extract was found to be rich in it. Auxin increases in amount in the hen's egg during development. This extraordinary parallelism between growth and auxin content is of great interest, but there is no direct or indirect evidence that growth of animal cells is in any way affected by the auxins.

THE SITE OF PARATHYROID ACTION

Does the parathyroid hormone act directly on the bones or does it primarily affect the kidneys? The question is still unsettled. Convincing evidence for both theories has been brought forward in the past, and it is typical of this problem that two recent investigations have led to opposite conclusions. Selye¹² still adheres to the older view—that the parathyroid hormone acts primarily on bone. In his experiments he injected 60 to 100 U.S.P. units of parathyroid hormone into rats 18 to 27 hours after nephrectomy. The animals were killed 32 to 36 hours after the operation, and even in this short time there was histological evidence of osteoclastic absorption of bone. There was, however, no calcification of the soft tissues, apart from calcium deposits detected histologically in the renal tubules of unoperated control rats: this is evidence that calcification of the soft tissues is a secondary action shown only when the kidney cannot excrete all the calcium and phosphate liberated from bone. Similar but much slower osseous absorption was produced by nephrectomy itself. Selye was able to show that this was probably due to a stimulation of the para-

thyroid glands, because it did not occur when they were removed at the same time as the kidneys. All in all, the experiments show that the parathyroid hormone acts on the bone, and that the kidney exerts only a regulatory effect probably depending on the calcium or phosphate concentration in the blood.

The upholders of the renal theory emphasize the fact that when parathyroid injections are given the first sign is an increased excretion of phosphate and a lowering of blood phosphate, and that these effects always precede the rise in serum calcium. Collip, who was formerly an upholder of the bone theory of parathyroid action, has recently swung over to the renal theory. Neufeld and he have shown that parathyroid extracts will not cause a rise in serum calcium in rats, cats, or dogs in which the excretion of urine is prevented either by removal of the kidney or by ligating the renal vessels or ureters. In the rats this treated the normal fall in blood phosphate after parathyroid injection was transformed into a large rise. Confirmatory evidence of the renal site of action was the fact that the rise in calcium and fall in phosphate in the blood after parathyroid treatment in dogs were prevented when posterior pituitary extract was given in large enough amounts to cause anuria, and that in a cat with exteriorized ligated ureters the normal response to parathyroid injections was restored by cutting the ligatures. The rise in serum calcium may be prevented in normal dogs if sodium acid phosphate is given intravenously at a rate that maintains a constant blood phosphate level, which shows that phosphate rather than calcium metabolism is primarily affected. It is noteworthy that Neufeld and Collip did not study the bone histology of their animals, nor did Selye investigate the calcium or phosphorus metabolism of his rats. Finally, to add to the confusion, Fay, Behrmann, and Buck¹³ have reported their failure to demonstrate any effect of parathyroidectomy or parathyroid injections on urinary phosphate or creatinine clearance in dogs.

MEDICINE IN THE FRENCH COLONIES

Through the ages in all countries medical science has struggled for advancement to make the world a better, safer place for man to dwell in. Many medical men have been leaders in the resistance to Germany in the countries she has overrun in Europe. Our Polish allies have organized their medical school in Scotland, with their own medical journal. Now we read, with pleasure and admiration for those Free Frenchmen carrying on the struggle, the first number of the *Revue des Sciences Médicales, Pharmaceutiques et Vétérinaires de l'Afrique Française Libre* from Brazzaville, with an introduction by the Director-General. There are ten papers on a wide variety of subjects both medical and surgical. Of particular interest are the descriptions of the first recorded case of rat-bite fever in French Equatorial Africa and work on trypanosomiasis. Campourcy has found an extremely low infection rate of *G. palpalis* with *T. gambiense* in the Cameroons. Only 44 of 1,166 flies caught in different areas proved to be infective, with a comparative figure of 518 infections among 9,440 natives examined in the same areas. David and Pape, also in the French Cameroons, record two cases of congenital trypanosomiasis, said to be the first ones in which transplacental transmission has been established beyond doubt. The scope and interest of the articles in this first issue have laid a firm foundation for the success of this journal, which represents the spirit of Free France.

DIPHTHERIA PROBLEMS

The following is substantially a memorandum on some difficulties in diagnosis, notification, and treatment of diphtheria, prepared by the council of the Fever Group of the Society of Medical Officers of Health.

Artificial immunization has markedly reduced the incidence of diphtheria and minimized the severity of attacks in protected or partially protected individuals. The variation in the classical signs has increased the difficulties of diagnosis in cases exhibiting doubtful throat symptoms, and without evidence of complete immunization, as shown by a negative Schick test, immunity cannot be safely assumed; further diphtheria may occur, though comparatively rarely, in a Schick-negative person. There is a tendency to place undue reliance on the result of swab examination. The bacteriologist cannot distinguish between active diphtheria and the carrier state, and his report must be interpreted in the light of clinical findings. Doubtful cases should be examined for haemolytic streptococci and Vincent's organisms.

Disposal of Cases

Where the practitioner is reasonably certain of the diagnosis an adequate dose of antitoxin must be given at the earliest possible moment, normally in hospital, as it is advisable to give one maximum dose rather than a succession of smaller ones. Only where there has already been delay or there is likely to be delay in admission should the doctor give antitoxin. The fatality rate in diphtheria varies directly with the number of days elapsing between onset of the disease and the administration of an adequate dose of antitoxin. Antitoxin need not be withheld for fear of severe reactions: the modern protein-digested concentrated product rarely gives rise to serum-sickness or related phenomena.

All doubtful cases require continuous observation, during which there should be full bacteriological and clinical investigations; they should be removed promptly to a hospital where appropriate treatment can be given. The procedure adopted in many hospitals to-day is as follows: (1) Where delay in the administration of antitoxin would be dangerous it should be given immediately, before any bacteriological investigation; (2) where a delay of six hours would not be dangerous the Schick test should be performed, swabs taken, and antitoxin given six hours later; and (3) where a delay of one day or more would not be dangerous the Schick test should be performed and swabs taken, and antitoxin deferred until the results are known. In no case should reliance be placed on the swab alone; every suspected case when first seen must either receive antitoxin and be swabbed or must be Schick-tested and swabbed. When in doubt antitoxin should be given.

Doubtful Cases

An individual whose throat or nose is swabbed because of contact with an established case but who has no symptoms must not be classed as a case of diphtheria, notified as such, or sent to hospital merely on account of a positive finding. The procedure for dealing with carriers is fully described in the report of the L.C.C. Departmental Committee on the Nomenclature of Diphtheritic Diseases (1926), in which reference should be made. Routine swabbing of contacts, except in special circumstances—e.g., certain institutional outbreaks—is to be deprecated and should at any rate be restricted to those showing an unhealthy condition of the nasal or pharyngeal mucosa. The waste of effort, time, and material involved is not justified by the very occasional discovery of a healthy carrier.

One of the main functions of an infectious diseases hospital should be the admission of doubtful cases for observation and final diagnosis. The L.C.C. is prepared to issue instructions that "diphtheria observation" will be accepted as an adequate diagnosis for admission to its hospitals, and it is hoped that other hospital authorities will do the same. The public should be taught to realize that the doctor who sends a doubtful case to hospital for investigation is doing better by his patient than the doctor who waits for the result of swab examination. Refusal by hospitals to admit possible cases of diphtheria without a definite diagnosis may compel doctors to notify many about which they are doubtful as actual cases. At present the error in notified diagnosis is very large; it varies in different parts of the country, being in London about 35%. As the Registrar-General corrects only a minority of cases in which the doctor withdraws his notification, the discrepancy between the actual and the published figures of diphtheria incidence is a very serious one. Admission of cases for "diphtheria observation" will go a long way to end this. Medical officers of health of authorities which provide their own infectious diseases hospitals will have little difficulty in dealing with such provisional notifications, and in other cases it should be simple to arrange with the hospital authority and the Registrar-General for regular revision of notifications based on the final diagnosis. If this procedure is adopted a larger proportion of single-bed wards will have to be provided. Newer knowledge of infectivity has already made the large, undivided ward something of an anachronism, and the procedure suggested in this memorandum may help to expedite long-overdue improvements in fever hospital construction.

Nova et Vetera

THE HIPPOCRATICS

Hippocrates is an author revered rather than read. Half a dozen pregnant aphorisms remain in the memories of all physicians, perhaps a score in those of the bookish, but a reader tempted by these purple patches to go to the source is apt to be disappointed. Probably most will read the essay on Ancient Medicine with as much pleasure as a not too technical dialogue of Plato gives, but the collection (even the so-called "genuine" works) contains so much which only one learned in ancient philosophy can understand at all, that interest fails. Just as most know Euclid at second hand (in these days hardly even that), knowledge of Hippocrates must be derivative. Fortunately those familiar with Greek thought, from Galen's time to ours, have written appraisements which the world could read. *Hippocratic Medicine*, by the late Prof. William Arthur Heidel, belongs to this class. The learned author was not a physician, but there is little in this book a physician might not have written. Perhaps he is a little less conscious than a clinician or an epidemiologist would be of the difficulty of identifying the epidemic in *Epidemics*, VI, 7, cap. 1. It is tempting to identify, with Littré, an epidemic cough, followed sometimes by anginas and paralyses, with diphtheria, but the Greek author's insistence upon the frequency of nyctalopia is puzzling. In any case, "spotting" epidemics of the remote past is not much more than an intellectual game, and, as Prof. Heidel says, a description of symptoms, however accurate, is not enough.

Did the Hippocratics Over-simplify?

The value of this study is in relating the Hippocratics to their scientific contemporaries and predecessors and in making a comparison between the ideal physician of that age and of our own. Unlike some scholars, Heidel passes by the—to those not expert philologists—rather tedious questions of authorship and uses the whole Hippocratic corpus as material for his study. Naturally the picture he paints is not unlike those of great predecessors, but he does modify some features. He suggests, for instance, that the speculative element of Greek science and its reliance on analogy have been overstressed, and that actually the Greeks were more empirical than they have had the credit for being. Bacon's contemptuous reference to Aristotle as an experimenter has been taken more seriously than it deserved. "Bacon knew little of the way the human mind actually works and had not reflected on the difference between arriving at conclusions and presenting them for the acceptance of others." Most men who have done real research work (a class to which Bacon hardly belonged) realize that truth. Laplace, who was wont to condense an elaborate investigation into the phrase, "It is easy to see that . . .," gave a not very extreme example of a common practice. The often-praised lucidity of French scientific writers in comparison with Germans is partly due to the omission of steps, although the habit may lead to the danger Horace mentioned—in striving for brevity one becomes obscure. In medical writings the danger is not obscurity but fallacious lucidity; a beautifully written textbook may produce an ill-grounded sense of security. The Hippocratics—as the most famous of their aphorisms proves—knew that risk, but Prof. Heidel thinks that they did over-simplify.

The Ideal Physician

Looking back to that wonderful age it is clear that our ideal and the Hippocratic ideal were the same, not only ethically—that has never been questioned—but intellectually. The Hippocratics insisted on the importance of a complete picture. One does not treat a disease but a sick man, an individual, yet not an isolated individual but a member of a group. One must survey the whole field. That is our view too; but while the Hippocratics had the courage—or the presumption—to believe that the physician's own moral and intellectual resources would suffice to enable him to establish a diagnosis and apply or direct the application of the necessary treatment, we believe that this is not always true. The Hippocratics, of course, used

technicians; but as subordinates, much as a hundred years ago, or even less, physicians availed themselves of the help of chemists and pathologists. Now, on the intellectual plane, the relation is not of master and servant but of joint heirship. Yet it is still true that in the lives of most human beings the relation of physician and patient is fundamentally what it was in the age of Hippocrates. Those who are afflicted or distressed in mind, body, or estate do not look for comfort to groups but to individuals, not to a committee of the College of Physicians or of the Law Society, but to a doctor or a lawyer. That is why the ideal physician of the Hippocratics—the individual wise, learned, but humble-minded, and a lover of his fellow-man—will remain the ideal of us, of our children and our children's children.

Immunization against Enteric Group Fevers

SIR.—On reading the article on enteric group fevers in prisoners from the Western Desert as it appeared in the *Journal* of June 12, my attention was riveted by a point which escaped my notice when writing the paper and which ought to be duly recorded. South African troops are inoculated, not with Army T.A.B. vaccine, but with Grasset's T.A.B. endotoxoid. (It will be recalled that at the Annual Meeting of the B.M.A. in Plymouth in 1938 a session of the Epidemic Diseases Section was devoted to a discussion on immunization against enteric group fevers, in which Dr. Grasset and I took part.)

When troops from the Union of South Africa reached the Middle East in 1941 they had been immunized with Grasset's endotoxoid. The opportunity to make a comparison of the respective preparations (endotoxoid and T.A.B.) was too good to be missed, and, with the co-operation of the D.M.S., U.D.F. (Brigadier Orenstein), arrangements were made to continue inoculating and re-inoculating South African troops with endotoxoid, and to collect and compare the results with those from the rest of the Force. These figures have not yet been finally assessed, but there is no doubt that endotoxoid affords a high degree of protection.

A number of the prisoners in the Sidi Hussein camp—i.e., the South African troops—were therefore protected not by T.A.B. vaccine but by endotoxoid. As all others—exact numbers are not available, but they constitute the majority—were inoculated with Army T.A.B., the main argument of my paper is unaffected, especially as Grasset's endotoxoid shares with Army T.A.B. the basic principle of being made from virulent strains of *Bact. typhosum*.—I am, etc.,

J. S. K. BOYD.

Comparative Value of Phage and Sulphonamides in Acute Bacillary Dysentery

SIR.—The table published by you of the results of the treatment of bacillary dysentery with sulphaguanidine by Cols. N. Hamilton Fairley and J. S. K. Boyd in the Middle East (*B.M.J.*, 1942, 2, 674), and the earlier table of the results of Drs. R. Reitler and K. Marberg with sulphapyridine (*B.M.J.*, 1941, 1, 277), taken in conjunction with my own published results with phage (*Lancet*, 1929, 2, 273), permit of comparing the therapeutic value of these respective agents.

Translating the Reitler and Marberg records and the Compton records into the Fairley and Boyd notation, we get the comparative data of Table I. My publication, which goes back to the early days of phage therapy when one was feeling one's way, records 45 successes out of 62 cases treated, with the administration in the main of only 3 ampoules of phage spread over 3 days (one ampoule immediately, one first thing the following morning, and one the next morning—a totally inadequate dosage in terms of to-day). The table of "clinical records" accompanying the original typescript, which table the *Lancet* was then unable to publish through lack of space, is fortunately still available. To bring the records into line with the ill 1-5 days before treatment group of Fairley and Boyd on the one hand, and, on the other, with 8 or more stools in the 24 hours before treatment in this same group in the series of Reitler and Marberg, elimination has been made of 3

cases whose date of onset was not recorded, of 7 cases ill 6-10 days of 4 cases ill 12 days or more, and of 9 cases with less than recorded motions in the 24 hours before treatment. This leaves 2 cases, in the ill 1-5 days before treatment group of Fairley and Boyd, and with 8 or more stools in the 24 hours before treatment series of Reitler and Marberg, with which to establish the appropriate data concerning phage of Table I.

TABLE I

No. of Cases	Average No. of Stools in 24 Hours before Treatment	Average Time in Days after Treatment before Stools per Day were:		Treatment	Authority
		3-5	2 or less		
39	27.8	4.0	5.3	Sulphaguanidine	Fairley and Boyd (1942)
16	20.5	2.5	3.0	Sulphapyridine	Reitler and Marberg (1941)
22	17.1	2.4	3.1	Phage	Compton (1929)

The Fairley and Boyd records deal only with Shiga cases; the Reitler and Marberg records with Shiga, Flexner-Y, Sonne, Strong and Schmitz infections; while the Compton records represent primarily "bacillary exudate" findings, with, among specimen cultured, the isolation of Shiga, Flexner, Hiss, Sonne, Morgan, Gay-Harris, and Sal. Alex. 5 (Newcastle group) organisms.

For economy of presentation the above table deals only with acute cases, those of the ill 1-5 days group of Fairley and Boyd. The latter's "formed" stool column has been discarded, since the quality of being formed is of little significance in Middle East stool and represents no special criterion of cure. What does this table teach? It indicates the progress of cure, which is seen to be the more drawn out the larger the initial number of stools. If we define as index of improvement the ratio of the number of stools in the 24 hours before treatment to the number of days to reach normal limits, then the table permits us to calculate the comparative rate of improvement in the different series. When these calculations are made we get the data of Table II.

TABLE II

	Improvement Index. Daily Rate of Return of Stools to Levels per Day of:	
	(a) 3-5	(b) 2 or less
Fairley and Boyd	6.95	5.24
Compton	7.12	5.51
Reitler and Marberg	8.20	6.83

Table II. shows that the quickest daily rate of return to the status quo ante occurs in the sulphapyridine series of Reitler and Marberg, the phage series of Compton coming in second best, and the sulphaguanidine series of Fairley and Boyd a close third. I may be contended that the relatively slower rate of cure in the Fairley and Boyd series was because their cases were Shiga infections. But this contention can almost certainly be dismissed as an explanation, since it in no way holds true for the four Shigas in the Reitler and Marberg series (representing 1/5th of their total cases), where the treatment was with sulphapyridine instead of sulphaguanidine. Here we find a calculated average of 36.25 stool in the 24 hours before treatment for two Shigas ill in the 1-5 day group and two in the ill 6-10 day group (of the Fairley and Boyd table), with a reduction to the level (a) in an average of 3.25 days and to the level (b) in an average of 3.5 days—thereby providing for the Shigas of Reitler and Marberg, treated with sulphapyridine improvement indexes of 11.15 for (a) and 10.35 for (b). The corresponding improvement indexes for the Shigas of Fairley and Boyd, ill in their combined 1-5 and 6-10 days groups, are easily calculated to be: 6.21 for (a) and 4.65 for (b). Based on an average of 24.84 (66) stools in the 24 hours before treatment, with a reduction to the level (a) in an average of 4 (53) days, and to the level (b) in an average of 5.34 (63) days. See the more complete table of the Fairley and Boyd results (*Lancet*, 1942, 1, 20). The numbers in parentheses are those from which averages have been struck. These figures indicate an average return of Shiga stool towards normal at rates practically twice as rapid with sulphapyridine as with sulphaguanidine. Moreover, for infections with classical bacilli other than *B. shiga*, the Reitler and Marberg series provides daily improvement in the number of stools at rates of 8.51 for (a) and 6.47 for (b), thus indicating that their Shiga improved at a relatively more rapid rate with sulphapyridine than did their other cases.

The sulphonamide statistics of Fairley and Boyd, as well as those of Reitler and Marberg, are important: the former as serving 16

explode the myth about any superiority of sulphaguanidine over phage in the treatment of acute bacillary dysentery; and the latter as establishing that sulphapyridine can be the more efficient of the two sulphonamides. The phage statistics here dealt with are for from showing phage at its best, and are quoted for the want of any more recent. They relate to pioneer work by myself when one was feeling one's way with phage and dosage was being worked out. Since then we have not troubled to collect statistics for publication, the Alexandria community having become, and having remained, so phage-minded as to render any further proof of the efficacy of phage unnecessary. With the perfected phage preparations available to-day, and administered every 3 or 4 hours in the acute stage, attacks of bacillary dysentery have become matters of little concern (see Compton, *B.M.J.*, 1941, 2, 280). Whatever may be the merits of the sulphonamides in bacillary dysentery, few practitioners with any genuine experience of good phage preparations will, I think, want to change their accustomed line of treatment with phage for sulphonamides, unless it be in the occasional chronic case that may not respond straightway to phage.

A final word. The Services would appear to have been let down over sulphaguanidine through insufficient supplies. Thus in your report Col. Fairley is reported as saying: "*If supplies were sufficient* [the italics are mine] the therapeutic ideal from the Army point of view was that every dysentery patient should have sulphaguanidine at the earliest possible moment." Now, since, on the showing of the Army's own statistics, sulphaguanidine possesses no advantage over phage in acute dysentery, why should not an enlightened phage policy—even an eleven-hour affair—be now embarked upon? And the more so since inexhaustible supplies of phage could without much difficulty be made available, if the Services so wished, with untold benefit to our fighting men of all three Services.

—I am, etc.,

Alexandria.

ARTHUR COMPTON.

Site of Embolus after Spinal Anaesthetic

SIR.—Major H. Agar in his article on peripheral arterial embolism (July 24, p. 101) makes the point that he employs spinal anaesthesia when performing embolectomy in the lower limbs. He does not say how long before operation the anaesthetic is given.

In the past year I have seen two cases treated by spinal anaesthesia and immediate operation. On each occasion when the vessel was exposed at the judged site of the embolus it was found that the embolus had moved peripherally owing to vasodilatation. I therefore believe a better method is to give a spinal anaesthetic in the ward, leave the patient for at least half an hour, and then redetermine the site of the embolus. By so doing it is possible that it may have moved sufficiently far distally for operation to be unnecessary.—I am, etc.,

St. Thomas's Hospital, S.E.1.

RAYMOND DALEY, M.R.C.P.

Eve's Method of Artificial Respiration

SIR.—Dr. Eve's method of artificial respiration has received welcome and deserved publicity during the past months, but it is unfortunate that so many of its advocates are concerned with apparatus. The method was first used on board a ship on Nov. 6, 1933, at the Falkland-Isles, a few weeks after the publication of Dr. Eve's second paper (*Lancet*, Sept. 30, 1933) and before the brilliance of his simple description had been obscured by a great cloud of witnesses or encumbered by an ever-growing literature on apparatus. My reason for drawing attention to this case is that it remains, to the best of my knowledge, the only one in which Eve's method has been used at sea during the ten years that have passed since the method became available. Until more cases are reported on it does not seem profitable to theorize on apparatus, and it may be excusable to quote what actually happened on this occasion.

Dr. Eve's principle was applied within five minutes of the occurrence of respiratory failure, and artificial respiration was maintained successfully and without effort for two hours, being abandoned only when circulatory failure was added to cessation of natural respiration. Details of this case were published (*J. roy. nav. med. Serv.*, 1934, 4, 20, 365) and the method thus commented on: "Its use in an emergency, in which there may be several cases of asphyxia to deal with at the same time, is only limited by the number of stretchers and hands available for rocking." Had the method at that time been so closely identified with ideas on mechanical appliances as

it is to-day it would probably not have been attempted with improvised equipment, on the score that such substitutes would be too clumsy and ineffective.

In the latest addition to communications on appliances Dr. J. R. Lahiff (July 10, p. 42) has produced an ingenious and simple piece of apparatus, but his suggestion that all stretchers should be so fitted and that this would effect a great saving of life is open to two objections. The number of cases of asphyxia in relation to the total numbers for which stretchers are used is negligible and the universal modification of stretchers for this purpose is not, therefore, reasonable; if, on the other hand, a case of asphyxia occurs in the absence of a stretcher so modified, lives may be lost through the idea gaining ground that the method is impracticable with improvised means. It is relevant to remark that such cases usually occur in wartime in groups, that, therefore, several modified stretchers might be required, and that for this reason the modification of a single stretcher in each ship would serve no good purpose.—I am, etc.,

London, E.C.4.

J. J. KEEVIL.

Adolescent Spondylitis

SIR.—Dr. C. W. Buckley (July 3, p. 4) devotes a considerable proportion of an article on the differential diagnosis of spinal arthritis to that form for which the late Dr. Gilbert Scott proposed the name "adolescent spondylitis." But Dr. Buckley does not confine himself to diagnosis. He gives a paragraph on treatment. As this summary appears to me to be unduly pessimistic, I have been hoping that someone would criticize it in your columns. But as this expectation has not so far been justified, I should like to offer a few remarks. They are based on an experience of some hundreds of cases.

To advise patients in early cases to rest in bed, unless for a very brief period, is to run the risk of their losing movements which they may never recover. Rest of itself will not check the disease, and if proper measures are taken it should seldom be necessary. The most effective treatment is that introduced some ten years ago by Dr. Scott. This has nothing to do with "deep x rays," but consists in the exposure of the whole body to subreaction doses of x rays generated at about 100,000 volts. He called this procedure "the wide field method." If this form of treatment is properly carried out the prognosis in adolescent spondylitis is good, as at least three-quarters of all early cases show a rapid and satisfactory response. Of those which do not, there are, in my experience, some who will nevertheless benefit by vaccines.—I am, etc.,

London, W.

F. HERNAMAN-JOHNSON.

Planning of Medical Education

SIR.—I have reread Prof. F. Davies's article (May 1, p. 547) in the light of his letter (June 26, p. 800). I am tempted to repeat my question: "Are we never to test the student's powers of co-ordinating the anatomy of the body as a whole?" If the answer is in the negative Prof. Davies should say so; if in the affirmative, then how are we to do this if we dispense with the 2nd M.B. examination as he suggests?

It is certainly not true of one university (Birmingham) to say that students of anatomy are "fully engaged right up to the eve of their professional examinations in acquiring new minute details and attempting to revise old ones already noted." Our students complete their dissections by the end of the fourth term, and during the fifth term are wholly engaged in correlating the observations made during the course of their investigations.

Prof. Davies speaks in his original article of students "crawling along" and objects to my reminding him that students do not now do this. Machinery has been instituted to dispose of the inept student without vocational aptitude at the "subacute" stage, and I do not believe that any medical school is likely to revert to the bad old days of the "chronic"; therefore this argument is not relevant.

I entirely agree with Prof. Davies as to the advisability of interviewing candidates, but that this should be undertaken by a committee (with or without representatives from other faculties) is not practicable because of the time involved. Since the results of many of the entrance examinations (Oxford and Cambridge School Certificates) are not declared until the eve of the new session, interviews cannot be postponed until after

these results are known. Thus we cannot wait for the weeding-out process of the entrance examinations, and all candidates must be interviewed. I am about to devote the major part of the summer vacation to this work, which, besides tact and patience, needs enthusiasm. I have most encouraging evidence from entirely neutral sources that this time is well spent. My work is simply to collate details concerning each applicant and to submit these to a selection committee, who make the final choice. In making our decision we have found a searching questionnaire sent to heads of schools most helpful.

I was surprised to learn from Prof. Davies that I am guilty of placing a *premium* on feats of memory. I must confess I do not despise the memory, indeed I realize it forms the basis of all knowledge: *Memoria est thesaurus omnium rerum et custos*. If Prof. Davies only knew how we eschew placing a *premium* upon memory, and if he knew of the efforts made here to discourage students from sharpening this faculty on barren anatomical flints, he would realize that he would be hard pressed to prove his assertion.

At this critical period in the world's history we are as alert to the prospect of the door of opportunity opening before us, perhaps-quite suddenly. We want to be prepared; we are neither self-satisfied nor complacent. We realize that in every walk of life there are wrongs to be righted and improvements to be made. We should, however, be grateful, as we grope forward in the darkness, for the voice that whispers *Festina lente*. We should not mind if when we venture an idea someone is unkind enough to criticize; rather should we

"Welcome each rebuff
That turns earth's smoothness rough,
Each sting that bids not sit nor stand but go!"

Destructive criticism if you like, but offered in response to the invitation given in the last paragraph of Prof. Davies's original article; not unkindly meant, and abundantly justified if by this we may be prevented from taking but one false step.—I am, etc.,

Birmingham.

C. F. V. SMOUT.

The People and State Medicine

SIR,—I fully agree with Dr. J. C. Gillies's spirited reply to the criticisms voiced by the Labour Party (*Supplement*, July 17). At the same time I have, like most of us, including Dr. Gillies, considerable sympathy with the people's case. They are being badly served, not through the fault of the doctors. If the successive Ministries of Health, in their handling of National Insurance matters, had deliberately intended and manoeuvred to bring the panel system into contempt and make it the byword which another of your correspondents rightly says it has become, they could not have done so more effectually than by their policy over the past thirty years. Perhaps it is so much to expect that they should understand either the people or the medical profession in directing our national experiment in State medicine. But even politicians and "pen-pushers" are aware that if a good service is wanted in any department of life it has to be adequately remunerated. By persistently ignoring this common-sense aspect the Ministry of Health has given some colour to the suggestion that it was hoped the panel system would fail and thus create a demand for a State-controlled service. In any case such policy has overreached itself. Whatever the nation wants, it does not want to be put "on the panel."

For the high policy that has directed this "twopence a week" service, misnamed National Health, I have had, though participating in it for fifteen years, little but contempt. I fled from the impossible hypocrisy of it in the Midlands of England to a State service in one of our Colonies, where I formed the opinion that in the matter of medical attention on the whole the Chinese and Indian coolies were getting the best of it. When perforce I returned home to general practice I took care that my panel should be small and so well offset by a prosperous population that I would be financially independent of the restrictions of N.H.I. practice, and so in a position to make no difference, whether in time spent or in remedies employed, between panel and private.

Of course such a policy is the best policy all round. No doctor wants the illness of a contract patient to drag on if it can be cut short. Here a good example of incompetent direction and interference with the doctor by the minions of the Ministries falls due to be publicized. Panel doctors were informed by an expert that liver injections were only to be used in the hyperchromic anaemias.

The treatment for the hypochromic type was iron. Good doctors, in a year's work, save more lives and relieve more serious sickness by injecting liver extract in the forbidden groups than in frank cases of Addisonian anaemia. Even before Prof. Davidson's brilliant work on the nutritional anaemias came out, even before this war brought its insidious attack on certain individual metabolisms which had come to depend on a high animal diet, it was only common sense to give an occasional jag of liver preparation to the debilitated dyspeptic or the milk-fed convalescent. It is, perhaps generally known that a timely injection of liver will prevent and even cut short attacks of angina pectoris; but presumably the Ministry's expert did not know this. Myself, I am still in the humiliating position of having to wangle some liver extract somehow for panel patients who would be the better for it but are not frank pernicious anaemia cases.

To produce more gravamen for my charge: what is the result when a new keen doctor comes to a district and gets a reputation for thoroughness? His panel becomes loaded with chronics and undiagnosed cases from miles round, not to mention the neurotics who are in search of *aliquid novi*. The system has a way of ensuring that the better work a doctor does the more will he be swamped with underpaid contract work. And, since there are only sixteen working hours in the day for most of us, he has no time for the more remunerative work and finds it hard to make a decent living. This means less comfort for himself, shorter holidays (the leisure that sweetens the day has long since gone with the wind), petty economies in the replacement of drugs, dressings, and the expensive tools of his craft, not to mention books. He degenerates into the kind of doctor that the "twopence a week sickness club" legislates for and ultimately gets.

I have often asked myself (having run away from slum practice twice), Is it possible for a man who can live and bring up a family on, say, £1,000 a year to limit his panel to 2,500 and, refusing private practice, make a good job of it? The answer is, No! First, he has the dependants to reckon with, mostly poorly paid practice that gives him little or no help with his financial budget. Secondly, the night-work, thanks partly to the necessity for certificates "on the dot," is more than an ordinary man can stand. Thirdly, he has the consultants to reckon with. These gentlemen, with whom as individuals I have no quarrel, are also in a position of having to earn a living in the few hours left them after the claims of hospital and dispensary work have been satisfied. (Incidentally, do the voluntary hospitals make sure, as they ought, that the approved societies and the Ministry do not exploit their charitable basis?) Now a doctor who has only panel patients, with his frequent demand for hospital beds (often urgently) and for diagnostic help which very often he should not require—for instance, how many panel doctors have time to use a microscope even on a urinary deposit?—such a doctor will not long endear himself to the specialist to the extent of being free of their wards and side-rooms, not to mention their firesides where so much good medical tuition is received and given. And so he, too, will degenerate into the "twopence a week" doctor.

Of this shoddy system the profession has tried up to now to make the best. Doctors have been, I think, very humane and generous almost to the point of hypocrisy in trying to conceal from the panel patient that poorly paid contract practice cannot be run on the same generous lines as private. We have accepted rebuff after rebuff from the Ministry. The last straw has been the inclusion of those with incomes up to £420—many of them on the telephone! That this class is to pay twopence a week for their doctoring is, on the face of it, absurd. We owe, even with a war on, no further loyalty to the Ministry of Health: we have kept silence and smoothed things over too long; the facts should be made public now. With the chance of reorganization before us it is our duty as a profession, no matter whose feelings are hurt. My own policy is now to let my panel patients know the limits of contract practice, throwing the blame where it belongs—on a Ministry that has dealt ungenerously with the doctors and can no longer expect them to deal generously with a system that only good will has made workable for so long. Any considered action the B.M.A. takes will, I am sure, be supported by the majority of panel doctors.

Actinomycosis of the Tongue

SIR,—In his interesting account of a case of actinomycosis of the tongue, which got better after treatment with sulphonamides, Dr. A. McCloy (July 24, p. 106) suggests that infection may have originated from a bullock which was suffering from "wooden tongue." This is unlikely, since it has for many years been known that the "wooden tongue" of cattle is due to infection with a bacillus, and the condition is known as "actinobacillosis."—I am, etc.,

Education and Health Services Areas

SIR.—In the suggestions for educational reform put forward by the President of the Board of Education county boroughs and county councils were mentioned as administrative areas. Now, while there is no objection to the former, there is undoubtedly strong objection to the latter—the county being the area—as community of interest is absent in such an area, and community of interest is vital for the success of all social organization and services, including education.

I therefore suggest that the county should be replaced by a region based on the university, which is really the true centre of enlightenment in the area served by it. To give examples of what I mean. Round Manchester and Liverpool in the North-West, Leeds, Sheffield, and Newcastle in the North and North-East, Birmingham in the Midlands, Bristol in the West, and Cardiff in Wales, etc., educational areas or regions could be formed which would be really socially coherent and natural, for they would have as headquarters a university, which people would naturally regard as their cultural and educational centre. The university region or area could also be the area for other administrative activities, such as public health and the new State Medical Service, as in it there would be the medical school, the large hospitals, special hospitals, and laboratories with their staffs of highly qualified physicians, surgeons, and specialists. It is with these institutions that the local health centres would be linked, and to their trained staffs that the local practitioners would naturally turn in difficult cases for advice and treatment and, where necessary (through research laboratories and high-powered x-ray units), investigation, it being remembered that ease of access and contiguity are important if these facilities are to be availed of.

The region formed of closely grouped local areas round a large town has another big advantage over the county with its scattered local units. In the Manchester area, for instance, under the county scheme Ashton-under-Lyne's headquarters would be Preston, for Hyde and Stalybridge it would be Chester, and for Glossop, Derby; yet all these towns are within 6 or 7 miles of each other and all except Glossop (which is 12 miles off) are about 6 miles from Manchester. Similarly in the Birmingham area Dudley, Bilston, and Sutton Coldfield would have headquarters at Worcester, Stafford, and Warwick instead of Birmingham with all its comprehensive medical facilities. Arguments of a similar nature would hold for town planning, which has an important part to play in post-war social organization. Are three different town-planning authorities going to plan for the satellite towns of Manchester, and three different ones for those of Birmingham? Surely all this would be fantastic, and in times of revolutionary change present realities should guide us. The county had its uses in feudal days, but feudal days are surely over. Let the Government, then, employ reason and courage in planning for education and health and our civic life.—I am, etc.,

Glossop.

Health Services in the Future Social Order

SIR.—There are still a number of medical men who, while taking a keen interest in the future of this country's health services, appear to overlook the fact that the fundamental issue is not a purely domestic one. Some of them not only ignore the political aspect of the matter but even seem to adopt a scornful attitude towards anyone whose vocation or discretion it is to notice overriding political considerations.

It is time all medical men took a wide glance at the political arena of which their own present transition is a part. The world, and particularly this country, is moving rapidly towards the attainment of certain social aims, chief among which is the equal enjoyment by all men of at least the essential amenities of life. The provision of such amenities will be increasingly demanded of the State, and the tendency will be to discourage private and subsidiary enterprise in connexion with them. That outcome is no longer just a socialist mirage, but probably represents the actual aspirations of a majority of the present electorate of this country. In any case it is a virtual certainty that in the course of the next twenty or thirty years medical and other essential services will become entirely a State responsibility. The medical profession must

face the fact that, like all other institutions, it is borne on the flow of this political tide. Its internal energy should be used to pilot it in mid-stream rather than dissipated in futile attempts to resist the current. If a complete State service is inevitable in the long run, it would be far better and more dignified for the profession to plan it now than to capitulate to the idea by uneasy stages.

There are people who appear to imagine that we have only to make up our minds what sort of medical service will suit us best and the Government will then pass the necessary laws to put it into force. They urge delay pending demobilization, not in order to consult the wishes of a large section of the community at present abroad; not even with the object of adding a certain amount of medical experience to their own; but primarily because they feel that it is important that the future medical service should provide the sort of professional life desired by the younger generation of doctors who will see the most of it. Others (often heard inquiring "Who started all this?") seem to think that their contentment with their present position provides adequate justification for their opposition to anyone's desire to change it in any way. What such people do not seem to realize is that we shall have to deal with a Government whose mandate is derived from a somewhat wider and less stable body of opinion than that to which they subscribe. Thus the planning of medical and other essential services might not be designed primarily to suit the private interests of those who may be called upon to run them.

The Government must be well aware that both inside and outside the House of Commons there is a highly critical consensus of opinion somewhat impatiently waiting for action to implement their promises of social reform. This majority would be quick to discern any sign that might indicate that it was trying to preserve the *status quo*. In fact the Government's practical intentions in relation to the demanded reforms will naturally be judged by what is achieved in its first attempt to put any of them into operation. It would appear that the new health service is likely to be the first practical example of the sort of social order this Government intends to create. Thus medical reform, far from being a domestic matter, might well provide one of the most important political issues of this decade. The effect of this will be to widen and intensify the scope of every question. For example, whereas retention of private practice might have been tolerated as an anachronism best left to die a natural death, it might now be hailed as a certain indication that the Government intended to cater for sectional interests generally and in a way that would perpetuate the reservation of a super-service in life's essentials for the benefit of a small and wealthier minority. In spite of such possibilities there are many medical men who, while believing that this Government represents them better than any probable alternative, nevertheless persist in urging a policy that might even contribute to its downfall.

However much we may dislike this mixture of medicine and politics it is obvious that the new medical coat will have to be cut according to the political cloth. It would therefore be as well if members of the profession took the measure of the stuff before deciding what range of patterns is available for their future habit.

Refresher Courses for Service M.O.s

SIR.—For some months now your *Journal* has been debating how to make the medical profession shipshape and seaworthy at the end of the war. There is one suggestion which I believe to be important. When I qualified I took the usual underpaid house post, and was then conscribed at the end of the sixth month. In those six months I had just enough time to heave overboard all the twaddle that one must swot up in order to pass one's finals, and was just beginning to find my feet in medicine when I was called up. Ever since then I have been serving in one of His Majesty's more skittish destroyers, and proud to be a member of her gallant company, but as for medicine—well, if I do an hour's work in the sick bay I congratulate myself on having had a busy day.

Surgical experience of a special kind may be obtained during the war, but few of us will be lucky enough to get a job where medical experience can be obtained to any great extent. It therefore appears to me, Sir, that in these discussions about patients getting better and more elaborate treatment after the war, a thought should be given for the flood of young doctors, who, through no fault of their own, have forgotten all their medicine, and who will descend upon the diseased section of the community with, most of them, neither the time nor the financial stability to take a refresher course. So I suggest that we try to make the State realize the necessity for

continuing our relatively generous Service pay for at least six months after demobilization on condition that we take that time in attending, preferably, refresher courses on medicine and allied subjects specially planned for us (e.g., ear, nose, and throat diseases).

It may be argued that we can easily keep in touch with modern progress from our medical journals and revise the already known from our textbooks. The first, however, requires a postal service infinitely more efficient than our present one (at any rate in this theatre of war); while as for the second—well, most of us have been medical students in the much too recent past for us to revert to reading about diseases without actually seeing them. Finally, it may be said that this is what house appointments are for. The number of these available, however, would be quite insufficient for the demand, nor do I see why a man should be rewarded for the services he rendered on active service and for the enthusiasm he now shows in his profession by the inadequate pay and—so frequently—hopeless living conditions of the average house-officer. In many cases, on the strength of the better Service pay and allowances, he may have married during the war, which would make his getting a house job quite impossible unless he happens to have a private income, and for that lucky man my suggestion is not made in the first place.—I am, etc.,

R. MOYLE,
Surg. Lieut. R.N.V.R.

Radiological Practice in a Comprehensive Medical Service

SIR,—In view of the probability that a comprehensive medical service may be introduced by the Government it is generally felt that the time has arrived when further steps should be taken to safeguard the interests of medical radiologists in such a service. We therefore invite medical radiologists to a mass meeting to be held on Saturday, Aug. 7, at 11 a.m. in the Reid-Knox Hall at 32, Welbeck Street, London, W.1 (by courtesy of the President and Council of the British Institute of Radiology). At this meeting all those interested in the future of radiology will have an opportunity of expressing their views as to the most suitable means of safeguarding their interests.—We are, etc.,

R. E. ROBERTS.
J. DUNCAN WHITE.

London, W.

Medico-Legal

SPACKMAN DECISION: APPEAL OF G.M.C.

HOUSE OF LORDS' JUDGMENT RESERVED

The House of Lords, consisting of the Lord Chancellor (Lord Simon), who presided, Lord Atkin, Lord Macmillan, Lord Tomer, and Lord Wright, heard on July 19, 20, and 21 the appeal of the General Medical Council against the decision of the Court of Appeal¹ which, on June 18, 1942 (reversing an order of the King's Bench Divisional Court²), quashed the direction given by the Council to erase from the *Medical Register* the name of Dr. Eric Spackman. After a decree of divorce had been granted to a Mr. T. C. Pepper in a suit in which Dr. Spackman was cited as co-respondent, the Council, on November, 1941, accepted Mr. Justice Langton's finding of adultery and refused to allow Dr. Spackman, who admitted professional relationship, to call further evidence challenging the issue of adultery, on the ground that such evidence was available and could have been given before the Divorce Court. The issue was whether in those circumstances the Council made "due inquiry" as prescribed by the Medical Act before coming to their decision. Mr. Charles Harman, K.C., and Mr. Douglas Bartley appeared for the General Medical Council. Dr. Spackman was represented by Mr. Cecil R. Havers, K.C., and Mr. Henry C. Dickens.

Mr. HARMAN said that the case raised a point of great importance to the Council, which had to act in a judicial

capacity in dealing with alleged misdemeanours of members of the medical profession. The point was a narrow one in that it turned upon the construction of Section 29 of the Medical Act, 1858, but it also involved the question of natural justice or, as it was called by some, substantial justice. Dr. Spackman complained that natural justice had not been done. The question was whether there had been "due inquiry" as laid down in the section.

The facts were that Mrs. Pepper brought a suit for divorce in 1939 on the ground of her husband's cruelty. The husband put in an answer denying cruelty and cross-petitioned for divorce, alleging adultery with Dr. Spackman during the period 1934-8. The hearing before Mr. Justice Langton occupied ten days. In the result the judge pronounced a decree in favour of the husband on the ground of adultery in 1938, stating that in his judgment the "adultery was not open to any reasonable doubt at all." At the Council inquiry which followed, Mr. Oswald Hempson, for Dr. Spackman, desired to call further evidence to answer the charge of adultery. He admitted that this evidence could have been made available to the Divorce Court, and that if he himself had been conducting the case in that court it would have been called. Mr. Hempson further contended that under Section 29 there was a distinction drawn between a conviction and the judgment of a "civil" tribunal such as a Divorce Court (which was not a conviction), that the Council was not bound by the decision in the Divorce Court, and was entitled to call further evidence. The Council, however, refused to hear the evidence on the ground that it could have been called in the Divorce Court, and that no special circumstances had been shown to exist for admitting further evidence on the adultery issue.

Lord ATKIN said that the charge on which Dr. Spackman was brought to the Council was for committing adultery. How, then, was he to meet it?

Mr. HARMAN said that the essence of the charge was that it was adultery of which he had been found guilty by the Court.

The LORD CHANCELLOR said that in the notice of inquiry sent to Dr. Spackman there was a paragraph which stated that "any answer, admission, or other communication or application which you may desire to make respecting the said charge or your defence thereto" should be sent to the Council's solicitors. The defence might be, "The charge that I committed adultery is untrue. I never did." Could the Council retort by saying, "We cannot allow you to say so because the Divorce Court found you guilty"?

Mr. HARMAN submitted that a body such as the Council was entitled to lay down rules for its practice and to say that where a matter had been considered by the High Court the court's decision should be accepted unless there were special circumstances such as that fresh evidence had been brought forward since the hearing.

Lord WRIGHT: Do you say that the decree is sufficient to establish due inquiry, or do you say it depends on the circumstances of the case?

Mr. HARMAN replied that what was "due inquiry" must depend in every case on the particular circumstances.

Lord ATKIN said that the point here seemed to be that Dr. Spackman wanted to call evidence and the Council would not let him. It seemed a denial of justice.

Mr. HARMAN pointed out that Dr. Spackman had had the opportunity of calling this evidence at the Divorce Court.

Lord MACMILLAN: That is not the point. We are concerned with the conduct of the General Medical Council.

The LORD CHANCELLOR said it was mentioned by the Lord Chief Justice in the Divisional Court that the Legal Assessor of the Council informed Mr. Hempson that it was the Council's practice to accept, *prima facie* at least, the decree nisi as evidence of adultery, and the onus was on Mr. Hempson to show special grounds why the Council should not accept it as such.

Lord ATKIN: I should have thought that was not allowing him to meet a *prima facie* case.

Lord WRIGHT: If witnesses had been called or if only a written statement had been put in and the Council had said, "Well, having read the statement we do not think it helps us at all." would there have been any complaint then?

¹ *British Medical Journal*, June 27, 1942, p. 806.
² *Ibid.*, April 18, 1942, p. 510.

Mr. HARMAN said that it was easy to be wise after the event. He was not denying that it would have been advisable, as things turned out, to have admitted the evidence, but that was not the point. The question was whether there had been substantial miscarriage of justice.

Lord ATKIN: The point is whether there was due inquiry.

Mr. HARMAN said that one could not conceive that if the additional evidence were likely to have been helpful it would not have been called in the Divorce Court in a contested case. It was odd to suggest that while the Council might safely abide by the decision of a petty sessional court on the smallest criminal matter it must not rely on the decision of a division of the High Court. When such a division was specially deputed to try this particular issue of adultery and was eminently qualified to do so, the Council was entitled to rely on the decision of that court. In what circumstances could it be said that the whole issue ought to be canvassed over again? When an accused man wanted to deny the charge afresh he thought the Council might well take as its example the Court of Appeal, and say that this was not a special circumstance entitling the accused to call evidence which was available but was not called at the trial. The right test to apply was whether the decision offended the ordinary man's sense of justice.

Mr. CECIL HAVERS, for Dr. Spackman, said that in almost every profession other than the medical there was a statutory right of appeal from the decision of its disciplinary body, but from the decision of the General Medical Council there was no appeal. He did not criticize the standing order of the Council relating to procedure at inquiries; his criticism was that, having made excellent rules, the Council failed to comply with them. What weight was to be attached to the further evidence was entirely a matter for the Council, but the Council must hear it. In fact the Council did not even allow Dr. Spackman's solicitor to explain the nature of the evidence. According to the Act, due inquiry had to be made by the Council and by nobody else. The Council was no doubt entitled to inform itself of the procedure in other courts of law, but a practitioner confronted with a very serious charge was at least entitled to go before his own tribunal, to affirm his innocence, and to tender witnesses to corroborate his story. The Council did not hold "due inquiry" by ascertaining that a court had made inquiry.

Mr. HARMAN said that he would ask their lordships to hesitate long before adding a further burden to the heavy one already borne by the Council. The Council was entitled to rely on any help given by a decision in the High Court.

Their lordships reserved judgment.

PROOF OF NEGLIGENCE

A doctor was recently sued for negligence in the High Court. The plaintiff was the father of a boy who had been evacuated to Buckinghamshire and had fallen ill with diphtheria. He called evidence that the boy had complained of pain in his neck and throat on Sept. 5, 1940. The doctor did not suspect diphtheria and did not take a swab till the 13th. The pathologist's report took four days to arrive, and during the interval the doctor did nothing. On the 17th the boy was removed to hospital hopelessly ill with diphtheria, and he died two days later. The doctor did not go into the box or call evidence, and his advisers submitted that in the absence of medical evidence, none of which was called by the plaintiff, he ought not to be found negligent. From this proposition Mr. Justice Atkinson dissented most strongly. If it were sound, he said, the medical profession would be in an amazing position and the public would be hopelessly at their mercy. Everyone knew the difficulty of getting a medical man to give evidence against another; a poor plaintiff simply could not do it. The judge said it was the first time in his experience that a medical man charged with negligence had refrained from going into the witness box to explain, excuse, or throw light on what had happened. He awarded £75 damages.

From the available reports of the case it does not appear that the doctor's counsel took the conventional course of submitting, at the close of the case for the plaintiff, that no case had been made out for him to answer, and then of calling evidence if the judge ruled that a case had been made out. He seems to have relied on the absence of evidence of the standard of care and skill required in the particular circumstances. The judge, on the other hand, seems to have considered that by any ordinary standard of care and skill the doctor should have done a good deal more than he actually did.

Obituary

EDWARD PHILIP STIBBE, F.R.C.S.

After several months of suffering borne with that stoicism and cheerfulness so characteristic of him Prof. E. P. Stibbe died on July 24 at the age of 58 in his home at Gerrard's Cross. He was educated at Glasgow, Wyggeston School, Leicester, and Charing Cross Hospital, obtaining the diplomas of L.R.C.P., M.R.C.S. in 1908. For the next six years he worked over-seas, first as Government medical officer in Fiji, and then as a district medical officer in South Africa. During the war 1914-18 he was M.O. at the 1st Northern General Hospital, and in 1919 he became professor of anatomy at the University of South Africa. Returning to this country, he took his F.R.C.S. in 1925 and was senior demonstrator in anatomy successively at Durham, Liverpool, and University College, London, with Elliott Smith. He then went to the London Hospital, and in 1935 he became university reader in anatomy, subsequently proceeding to King's College, Strand, where he was appointed professor of anatomy. Besides many papers on medical, anatomical, and neurological subjects contributed to the *South African Medical Journal*, as well as to the journals here, Stibbe published, in 1930, *A Textbook of Physical Anthropology*; in 1934, *Anatomy for Dental Students*; in 1940, *Aids to Anatomy*. In 1932 he edited *Six Teachers' Anatomy*. He examined in anatomy for the L.R.C.P., M.R.C.S. (1933-8), for the primary F.R.C.S. (1936-41), and for the Universities of Durham and Liverpool, as well as for the Society of Apothecaries. He was a kindly and understanding examiner, as well as a great teacher whose wide experience of medical and surgical practice brought a vitality and interest to his teaching of a subject which is so often treated as mainly academic.

Stibbe (writes a friend) was a loyal son of the Royal College of Surgeons, by whom he was appointed Hunterian Professor for 1936, his lecture on Jan. 27 of that year being one of only four at which the attendance exceeded one hundred. What he regarded as one of his greatest honours was his appointment by the Royal College to be an examiner for the Over-seas Primary F.R.C.S., which was to have been conducted in India and Egypt during the winter of 1939-40. The outbreak of war, however, necessitated the cancellation of these examinations. Stibbe's affection for his students was a very real thing, and when, owing to the war, the medical faculty of King's was evacuated first to Glasgow and then to Birmingham, he it was who became the *paterfamilias*; nothing was too much trouble, either in term or vacation, from organizing vacation work "to help the war effort" to getting out his car at midnight in order to take a student with acute toothache to see a dental surgeon—picking up the dental surgeon *en route*. Of an unusually quiet and retiring disposition, Stibbe was a most lovable man with a profound sympathy and affection for his fellow men; it was a real joy to him to be able to help anyone who was in trouble; he was indeed the personification of Kipling's "thousandth man." The deep sympathy of his many friends goes to his widowed mother and to that gentle lady, his wife, who through all these months has by her own courage and cheerfulness helped to strengthen and comfort both him and his friends. The world is the poorer for the passing of Philip Stibbe.

Mr. GEORGE HAROLD LAWSON WHALE, who died suddenly on June 17, was for a long time surgeon for diseases of the ear, nose, and throat to the National Temperance Hospital and the Hampstead General Hospital. He was born at Woolwich in August, 1876, and was educated at Bradfield College, Jesus College, Cambridge, and St. Bartholomew's Hospital, graduating M.B., B.Ch. in 1902 and proceeding M.D. in 1907. He was a keen golfer, and at Cambridge played tennis for the University. He took the F.R.C.S. in 1912, on his return to civil life after holding a commission in the I.M.S. He then devoted himself to oto-rhinology and became chief assistant in the ear department at Bart's and assistant surgeon to the Metropolitan Ear, Nose, and Throat Hospital. During the last war he served in the R.A.M.C.(T.) as surgical specialist to No. 53 General Hospital, B.E.F. In 1915 he wrote jointly with Sir James Dundas-Grant on injuries of the throat and nose, and four years later he published a book *Injuries of the Head and Neck*, followed by a little work *Modern Treatment of Diseases of the Throat, Nose and Ear*. During the present war Mr. Lawson Whale was appointed by the Ministry of Health to deal with air-raid casualties at the Hampstead General Hospital under

the Emergency Medical Scheme, and in the course of his duties an incident occurred which obliged him to bring an action for libel against a gentleman who made a complaint in writing to the secretary of the hospital in regard to his conduct to certain patients who had been injured in an air raid. After evidence had been heard, Mr. Whale, through his counsel, stated that he was satisfied that the defendant had acted responsibly and throughout in good faith, and as his only object in bringing the action had been to clear his reputation he withdrew it, the defendant on his part expressing regret that the letter he wrote was too strong in its terms. The judge welcomed the settlement, saying he would not like it to be thought that this ending to the case reflected on Mr. Whale in any way.

We regret to announce the death in Cornwall on June 23 of Dr. JAMES ALEXANDER HENDRY, a former chairman of the Buxton Division of the B.M.A. He studied at the University of Aberdeen, graduating M.A., B.Sc., M.B., B.Ch. in 1908, and then, after holding a house appointment at the Nottingham General Hospital, went to Buxton in 1911, where by his ability and devoted attention he quickly won the respect and confidence of his patients. During the last war he served as captain, R.A.M.C., in Salonika, Mesopotamia, and France. Dr. Hendry's sound judgment and sympathy with the sick were recognized by all his colleagues at the Devonshire Royal Hospital, Buxton, and at the Buxton District Hospital; he served both institutions as physician and also as member of the committee of management. The news of his death came as a painful shock to his patients and fellow-practitioners, though it was well known that his retirement from active work had been caused by ill-health.

We regret to announce that Mr. CHARLES BERTRAM THOMSON, F.R.C.S., of Wimborne died on June 29 as the result of a road accident. He had practised many years at Wimborne as a member of the firm of which Sir Kaye Le Fleming is senior partner. He studied medicine at Guy's Hospital, qualifying M.R.C.S., L.R.C.P. in 1899 and taking the F.R.C.S. in 1905, after holding the posts of house-surgeon and obstetric resident at Guy's and clinical assistant at the Evelina Hospital for Sick Children. Among his other local appointments were those of certifying factory surgeon and police surgeon, and he had been M.O.H. for Wimborne and Cranborne Rural District. He joined the B.M.A. immediately after qualifying. Thomson devoted his life to his practice, which was large and widely scattered. The scanty leisure he enjoyed was occupied in the study of botany. He leaves a son in the medical profession, at present engaged on the teaching staff of Guy's Hospital.

Dr. ERNEST A. RAMSDEN, aged 61 years, of Saddleworth, Yorks, died on July 2 after six months' illness. From the Manchester Grammar School he won an Exhibition at New College, Oxford, in 1902, and after graduating as B.A. with honours in physiology was elected to a University Scholarship at Charing Cross Hospital in 1906. After taking the M.R.C.S.Eng., L.R.C.P.Lond. qualification and passing the final examination for the M.B. and B.Ch. degrees at Oxford, he served as a house-physician at that hospital and then joined his brother Herbert in medical practice at Saddleworth, and succeeded him seven years ago as medical officer of health for the Urban Sanitary District of Saddleworth. He was also certifying factory surgeon and medical officer to the Post Office. He acted for some months as a house-surgeon at the Manchester Eye Hospital. He was a good chess player and an enthusiastic member of the local geological society. He was the fifth and youngest son of Dr. W. H. F. Ramsden, the memory of whom is perpetuated in the Dobcross village square by a publicly subscribed fountain bearing as epitaph, "Write me as one that loves his fellow-men" (from Leigh Hunt's "Abou Ben Adhem").

Dr. HAROLD ALEXANDER MITCHELL, medical director of the Evans Biological Institute, Runcorn, died in Liverpool on July 2 at the early age of 52. Born in Canada, the son of a Presbyterian minister, Mitchell was intensely proud of being a Canadian. At the University of Toronto he graduated B.A. and M.D., and also took the diploma M.C.P.S. Ontario. Among his contemporaries were Prof. H. B. Maitland and Sir F. G. Banting. He came to this country with the Canadian Expeditionary Force during the last war, and was a captain in the C.A.M.C. At the end of the war he specialized in pathology and immunology, joined the staff of the Evans Biological Institute, and became honorary pathologist to the Warrington Infirmary. A colleague writes: Mitchell's vigorous mind and great personal energy soon made him a master of the difficult problems connected with the large-scale preparation of biological products. He inspired loyalty and keenness in all who worked with him, and his infectious smile and dry sense of humour will be long remembered. A true democrat, Mitchell

hated the "cobwebs" associated with hoary traditions, and firmly believed that the British Empire would be rejuvenated if the seat of government was removed from London to Toronto. Stamp-collecting was his one great hobby, and he had a very fine collection of stamps of the British Empire. Knowing himself to be a doomed man, Mitchell faced the latter months of a painful illness with heroic fortitude. He leaves a wife and two daughters. Mitchell was a major in the 15th Bn. Cheshire Regt. Home Guard, a Fellow of the Royal Society of Medicine, a member of the Biochemical Society, and joined the B.M.A. in 1923.

We regret to learn of the sudden death in Cairo on July 1 of Dr. AUSTIN WILLIAM BYRNE, expert in public health to the Egyptian Government, who was awarded the C.B.E. last autumn in recognition of his most helpful co-operation with the Medical Services of the British Army in Egypt in securing hospital treatment for prisoners of war. Dr. Byrne studied medicine in Liverpool, graduating M.B., Ch.B. of the University in 1906; he obtained the D.P.H. of Manchester in 1911 and the M.R.C.P. diploma in 1940. He had served in the R.A.M.C. with the rank of captain. During the war, in addition to his post as consultant to the Ministry of Health and technical adviser on quarantine administration under the Egyptian Government, he was appointed liaison officer between the Egyptian Government Medical Service and the R.N., Army R.A.F., and Allied Forces in Egypt. For some years past he had examined in public health and for the diploma in tropical medicine and tropical hygiene of the Medical School of the Egyptian University. In 1930 he recorded his investigation into the occurrence of plague in Alexandria.

Prof. THOMAS JOHN JEHU, M.D., F.R.S.Ed., who died on July 18, had a most distinguished career in the realm of science. Born in Montgomeryshire in 1871, he was educated at Oswestry High School and at the University of Edinburgh where he graduated M.B., C.M., and B.Sc. in Public Health and was medallist in Geology Class. He then went on to Cambridge, winning an exhibition and a foundation scholarship at St. John's College, and gaining first-class honours in Parts 1 and 2 of the Natural Sciences Tripos and a second-class in the Moral Science Tripos. In 1898 St. John's College awarded him the Newcombe Prize for Natural Science and Philosophy; two years later he returned to the University of Edinburgh as Heriot Fellow, and soon afterwards proceeded M.D. Dr. Jehu was lecturer in geology at St. Andrew's University from 1903 until his appointment as Regius Professor of Geology and Mineralogy at Edinburgh in 1914. After his retirement from the chair he was made Professor Emeritus. He was the author of important publications on the lakes of Snowdonia and Eastern Caernarvonshire, and on the glacial deposits of Northern Pembrokeshire and Western Caernarvonshire. A few years ago he carried out geological investigations in the Outer Hebrides with Dr. R. M. Craig, which won them the Keith Prize of the Royal Society of Edinburgh. He was a member of the Royal Commission on Coast Erosion in 1906.

Mr. FRED STOKER, formerly of Harley Street and before then in general practice, died at Loughton, Essex, on July 20. He studied medicine at Newcastle, graduating M.B., B.S. of the University of Durham in 1904, and taking the F.R.C.S. in 1907. In his student days at Newcastle he won three scholarships. He was for some years surgeon to Queen Mary's Hospital and surgeon to the throat and ear department of the Italian Hospital, and at the Annual Meeting of the B.M.A. in 1926 he was honorary secretary of the Section of Laryngology and Otology. After retiring from surgical practice Mr. Stoker devoted his time to gardening and botany and became well known in horticultural circles. He was the author of several books on horticulture, and for the past two years had regularly contributed gardening articles to the *Times*. In 1937 the Royal Horticultural Society, for whose journal he frequently wrote, bestowed upon him its Victoria Medal of Honour.

Dr. FRANK WILLIAM MARTIN, who died at his home in Springburn, Glasgow, was for 12 years attached to the Forensic Medicine Department at Glasgow University and held the post of divisional surgeon to the City of Glasgow Police. He was born at Bodmin, Cornwall, on Nov. 2, 1883, son of Frank Martin, F.S.A., and was educated at the High School and University of Glasgow, graduating M.B., B.Ch. in 1911 and M.D. in 1933. In the last war Dr. Martin served as captain R.A.M.C.(T.A.), was officer-in-charge of the Red Cross Hospital at Springburn, and later served with the 22nd Cavalry Division at Salonika. After the armistice he was medical referee under the Ministry of Pensions and held a number of appointments in and around Glasgow. He was honorary secretary of the Glasgow Eastern Division of the B.M.A. in

1926-9 and had been a member of the Glasgow Local Medical and Panel Committee. For some years he examined in forensic medicine for the University of St. Andrews.

News has been received from New Zealand of the death at Otago on June 21 of Mr. ALEXANDER TODD McCaw, surgeon to the Southland Hospital, Invercargill. He was born on April 9, 1881, son of Hugh McCaw, M.B., and was educated at Otago College of the New Zealand University. He came to England in 1905 and entered the London Hospital, where after qualifying M.R.C.S., L.R.C.P. in 1908 he served as house-surgeon and pathological assistant. Then after further experience at the Seamen's Hospital, Greenwich, he took the F.R.C.S. in 1911, and was for a year senior resident officer at the Bristol Royal Hospital for Children and Women. Mr. McCaw returned to New Zealand to take up surgical practice at Invercargill, and during the last war was in France for two years as captain in the New Zealand Medical Corps. He joined the B.M.A. in 1914 and was chairman of the Southland Division in 1934-6. He was elected F.R.A.C.S. in 1929.

Universities and Colleges

UNIVERSITY OF LEEDS

The University Court has resolved to confer the honorary degree of LL.D. upon Prof. H. S. Raper, F.R.C.P., F.R.S., who has been Brackenbury professor of physiology and director of the physiological laboratories in the University of Manchester for the past twenty years and formerly held the chair of physiology and biochemistry in the University of Leeds. This and other honorary degrees will be conferred on Oct. 27.

UNIVERSITY OF WALES

WELSH NATIONAL SCHOOL OF MEDICINE

The following candidates have satisfied the examiners at the examination indicated:

M.B., B.Ch.—*Surgeons*: S. C. Dymond, A. J. Evans, Elizabeth M. E. Evans, R. G. Evans, J. I. Hughes, F. C. Jenkins, A. E. Jones, C. R. Jones, C. C. Lewis, Gwenda M. Lewis, A. V. Lillywhite, Margaret E. Miller, Ivy M. Morgans, E. R. Price, J. F. Rees, P. H. Thomas, H. D. Walters, I. M. Watkins, A. A. Yauziskis.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

A quarterly meeting of the College was held on July 20 with the President, Dr. Charles McNeill, in the chair. Dr. James Macalister Mackintosh (Glasgow) was introduced and took his seat as a Fellow of the College. Drs. Henry Hunter Corrigan (Isle of Man), Ian Murray (Glasgow), James Innes (Edinburgh), Harry Stalker (Edinburgh), and Alexander Brown (Edinburgh) were elected Fellows of the College.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At a quarterly meeting of the Council held in the College House on July 24, with the President, Sir William Fletcher Shaw, in the chair, the following officers were elected to take office in October:

President: Mr. Eardley Holland. *Vice-Presidents*: Mr. William Gough and Prof. Daniel Dougal. *Honorary Treasurer*: Mr. J. P. Hedley. *Honorary Secretary*: Mr. G. F. Gibberd. Mr. William Gilliat was appointed Deputy Honorary Secretary in the absence of Mr. Gibberd on active service. *Honorary Librarian*: Wing Cmdr. F. W. Roques. *Honorary Curator of Museum*: Mr. Alec W. Bourne.

The following candidates were elected to the Membership: J. K. Baker, J. Kruger, Katharine I. Liebert.

The Council was gratified to receive the gift of £1,000 from a Fellow of the College who wished to remain anonymous. It has been given to commemorate the Presidency of Sir William Fletcher Shaw and the honour of Knighthood conferred on him by the King, and the interest from the gift will form a scholarship to be awarded triennially for research.

CONJOINT BOARD IN SCOTLAND

The following candidates, having passed the final examination, have been admitted L.R.C.P.Ed., L.R.C.S.Ed., and L.R.F.P.&S.Glasg.:

J. E. K. Butchart, J. B. Chetwynd, E. J. Connolly, P. M. Ellison, J. Honis, S. Hollowell, R. H. Johnson, W. S. Joyce, W. B. Kalish, P. D. Kemp, I. Le Vang, W. Levy, V. H. McGettigan, C. McKenzie, A. Marshall, P. Menko, T. S. Moore, H. D. Morgenbesser, C. E. Phillips, C. E. Ratner, W. M. Robinson, C. C. Rollason, A. Simons, B. Saeli, W. R. Steven, N. C. Wollin, M. Ziser.

The following graduates of recognized foreign universities were also admitted Licentiate: W. Hofer, M.D.Vienna, A. Levin, M.D.Munich.

Medical Notes in Parliament

Pensions: New Provisions of Royal Warrant

A debate on pensions and allowances took place in committee of the House of Commons on July 20, when Sir JOHN ANDERSON explained the new arrangements. He said that a very careful review had been made by the War Cabinet after the criticisms and requests put forward in the House and outside. As a result of the changes proposed, it would be found that all reasonable demands had been substantially met. The first and very important change recorded in the White Paper recently issued concerned the onus of proof. The Government proposed to redraft entirely the existing provisions of the Royal Warrant governing the conditions of entitlement to pension. The redraft included certain novel features entirely in the interests of the claimants. They established two presumptions: (1) that a man's condition as recorded on his admission to the Service was, in fact, his condition at that time; and (2) that any subsequent deterioration in his condition was due to his service. It was further provided that there should be no onus of proof on the claimant, and that the benefit of any reasonable doubt should be given to the claimant.

Two other important changes had been made. The word "directly" in the phrase "directly attributable" was omitted and the word "material" in the phrase "material aggravation" and "materially" in the phrase "materially aggravated" were also omitted. These would result in bringing within the scope of the Warrant cases which had hitherto been properly excluded. Any such cases which, under the new terms, became for the first time eligible for pension or grant would be reconsidered at once by the Minister on application. That included old cases which had been rejected. These changes, important as they were, did not go as far as some critics of the Warrant wished, and did not mean an acceptance of the slogan "Fit for service, fit for pension." The only cases that were excluded were those of disablement which were frankly not connected with or attributable to war service, although suffered after the commencement of war service. It would not be possible to stop short at disablements which had occurred during service. Disablements arising after service would have to be brought in, and that would create inequalities and give rise to new grievances. Such cases were proper for consideration under the general social services provisions.

The Question of Accidents

Sir John went on to refer to the sentence beginning: "While the Minister of Pensions would pay regard to any other evidence, including the consensus of medical opinion," and ending with the words: "he will give full weight to the general view expressed above." He said the Government had provided that there should be no onus put on the applicant, that there should be a presumption in his favour, but that, if they found a condition which doctors universally agreed was not attributable to war service, then rebutting evidence would be admissible, and the presumption with which they started might be overborne. With regard to accidents, the Government was giving the fullest application of the doctrine that a Service man placed himself wholly and unreservedly at the disposal of the State during his service, and they were covering everything, with one exception. The exception was the case of a man who went on leave, who was for the time being entirely released from his obligation to the State, and was just as free as anyone else to do what he liked. When soldiers were on foreign service their whole conditions of life would be covered. The Government had not been able to agree to the demand that there should be no distinction between the post-injury marriage and the pre-injury marriage. They had, however, decided to give an extra 10s. a week to the wholly unemployable man, whether single or married, plus allowances at the full rate for his wife and children irrespective of the date of marriage. If the pensionable disablement resulted in the pensioner's death a widow's pension would be granted. That would have to be applied to pensioners of the last war. The case of officers' family allowances would be dealt with by removing the present obligation to prove need. Officers would of course also benefit by some of the other changes that were being made.

General Insurance Provision for Services

Dr. HADEN GUEST said that the changes in the pensions Warrant were very great. Its old-fashioned structure was completely broken up, and the main purpose of the old Warrant was dead. While welcoming the White Paper because of the simplification it would bring in administration, he urged that the State

should accept an all-in liability for every kind of disease and disability of all persons in the Services. The Minister should set up an interdepartmental committee of the Ministry of Pensions and the Services to ascertain what the cost of general insurance provision would be and what the saving in man-power with regard to administrative services. If, as he believed, the amount of time spent in the Services in connexion with this sort of thing was out of all proportion—some said 10%—to the amount expended in war in the line, any economy in man-power would be of immense benefit. This would also be largely an economy in medical man-power, of which there was a great shortage.

Dr. H. B. MORGAN said that some of the work of the Ministry of Pensions had been beyond praise. For instance, the hospital at Roehampton was almost a model for certain institutions in the country. He was, however, rather perturbed about certain conditions in the White Paper. How was the Minister to get the independent medical opinion he desired? Medical views had changed. Medical men were seldom trained in questions of attributability, aggravation, or causation of disease. The difficulty of assessing causation, especially when causation was doubtful or not known, was extraordinary. There was no medical training on that point in this country. A great deal depended on the personal factor, such as on the man chosen or the composition of the appeal tribunals. Until there were "soldiers' friends," chosen by the appellants themselves or their organizations, the appellants would really never get justice, nor would there be really decent administration of pensions.

Scientific Research

In the House of Lords on July 20 the debate on a motion by Viscount Samuel calling attention to the need for the further expansion of scientific research was resumed. Lord DAWSON said that we must recognize the progressive momentum of discovery and invention during the last 60 years. In no like period of history had such vast changes taken place. After the last war research and discovery dropped into oblivion in the public mind, but from the moment this war began science had had full and ample recognition and support in every department of Government. After recalling several of the discoveries in the war, Lord Dawson referred to the close co-operation between the British Empire and the U.S.A. in matters of discovery and research. The results had been pooled, and an unselfish and generous anonymity had for the most part been observed. With the onset of peace there would assuredly be a great surge forward of new methods and of new ways. This country must meet the new needs. An organization would be required to make available the great store of talent which the war had disclosed, and to provide endowments on a correspondingly vast scale.

Speaking of the work of the Agricultural Research Council, the Medical Research Council, and the Department of Scientific and Industrial Research, Lord Dawson said that these bodies, being under the Lord President of the Council, were amenable to Parliament, yet they had that freedom which was essential to successful functioning. Most important of all, there was no administrative machinery between each body and the Minister such as would be the case if that body were enmeshed in the Civil Service and formed part of an administrative department. It was difficult to overstate the importance here science was concerned—and this applied equally to medicine—of preventing the enmeshment of any research body in the close entanglement of a Government Department. One of the chief reasons why these research bodies should receive further support was that they succeeded in combining good order in the work of men of ability with freedom for scientific investigation. He hoped that they would be given a prominent part in any further scheme of research which the Government ought fit to sponsor. It must be said that in the collective minds of the Civil Service there was an imperfect appreciation of understanding of what science stood for. Was not that due to the fact that those who entered the Civil Service under the aegis of science had not the same prospects of rising to the higher posts as those who entered by other portals? How could the Government service expect to get the best brains in science if they treated research and science in that undignified and unfair way? The time had come when the higher posts in the Civil Service should be thrown open to those trained in scientific research. That would attract the best minds, which the present hesitated to enter that service.

Medical Research

Referring to the Medical Research Council, he said its parish was a wide one. It far outstripped what he might call the narrower boundaries of medicine. It embraced the whole of the basic sciences on which medicine was founded, and in the

course of this war it had had a range of activity which would surprise many members of the House. It had whole-time workers on its staff, and had under its control the great National Institute for Medical Research, where large-scale work, requiring investigation by teams, was carried on. The institute had a world-wide reputation. It was recognized as the home of scientific standards the world over, and it was a centre of reference in that respect. It had played a leading part in advancing knowledge, notably in the fields of vitamins and hormones. Further, the M.R.C., through its grantees, supported research in medical schools in the universities and colleges in fact, wherever research was firmly rooted and well provided for. Its idea was to help the individual research worker who had proved his ability. It further co-operated through its committees with industry, notably with the Industrial Health Research Board, and a little while ago it founded a research professorship in industrial diseases at the London Hospital. The M.R.C. was also an admirable intelligence department. It knew where all the workers on the different subjects were, and it had the power to gather them together and rally them for a common purpose. Above all, its influence and its encouragement were far-flung over the whole field of medical progress.

There was no investment which offered better results to the nation than that of discovery and research. We might reckon that disease cost this country about £250,000,000 a year. The progress of discovery diminished the ravages and therefore the cost of disease. Some diseases, like rickets and diseased teeth were passing out of existence. Others, like diabetes, pernicious anaemia, and deficiency diseases, were now under control. Puerperal fever, which not long ago was a constant peril of childbirth, had steadily declined, and pneumonia had lost a large part of its peril and anxiety since the discovery of the sulphonic amides. Again, certain forms of meningitis, previously incurable, were not infrequently cured. Another example was gonorrhoea, which attacked people in the active period of life and caused disablement lasting for weeks. Now, owing to the drug in use, its cure could almost be guaranteed within three days. What was more important, the long-term complication of that disease could be almost entirely avoided. Finally there was penicillin, the discovery and development of which were entirely to the credit of British minds and British research workers. This path of chemotherapy was opening up more widely every month. It was opening up help in the direction of tropical diseases, and had played a great part in the improvement of treatment of wounds in the present war.

Government Research Workers

Lord CHERWELL said that we could not overlook the importance, from the economic point of view, of fostering pure fundamental research. The Government recognized that pure research must be, in a large measure, its responsibility and must be done at the universities; but naturally, as Lord Dawson had said, they also wished to encourage industry to spend money on pure research. It was the Government's policy and intention to increase its aid for research, and it would welcome any developments of industry in a similar direction. He hoped we might see another step forward in the place given to scientific subjects in our schools. The treatment of scientists in the Civil Service had been mentioned, and he frankly admitted that the Civil Service had not hitherto shown due regard for the contribution scientists were making to the nation's welfare. This matter had now been reviewed, and an investigation had been in progress to make sure that the conditions of service, pay, and prospects of Government scientific employees compared favourably with those on the administrative side. He hoped that a definite announcement on these reforms might be made before long. After all, we must preserve a sense of proportion. There were probably not more than a few dozen physicists in this country capable of evolving and developing new applications of, say, the various radio devices on which success in this war very largely depended. Everyone would agree that it was an anomaly to pay them on lower scales than men of equal educational status who, because they had distinguished themselves in what were usually called "humane" subjects, were often given war jobs of much higher status and pay than the scientist.

Mental Health of Recruits

Mr. WOOTTON-DAVIES asked the Minister of Labour what steps were taken when passing men as fit for Army service to ensure that the examining medical boards were fully informed of and took into account any past records of mental instability. Mr. TOMLINSON said that the instructions issued to medical boards provided for inquiry to be made into a man's personal and family history of nervous and mental illness, and for a specialist's opinion to be obtained in cases of doubt. In addition

tion, since October, 1940, every recruit had been asked to complete in writing a questionnaire, which included two questions specially directed to this subject. Since December, 1940, the Department had been notified by the Board of Control of all men who might have become liable for military service by reason of their discharge from Orders under the Mental Deficiency Acts, and in all such cases the man's history was brought to the notice of the medical board. Men who exhibited indications of a high degree of nervous or mental instability, or who had at any period of their lives been certified to be of unsound mind or about whom there was other convincing evidence of past or present insanity were not called up for military service.

Beds for Tuberculous Patients in Wales.—Mr. BROWN, replying to Mr. Ness Edwards on July 15, said it was anticipated that within the next few months at least 800 tuberculosis patients in Wales would be waiting for hospital accommodation. The figure was an estimate, but there was at present a substantial shortage of beds for tuberculosis cases in Wales, as in other parts of the country. The problem was greatly accentuated by the present necessary restrictions on new building, and by the difficulty of providing hospital staff. With the help of the Minister of Labour and National Service, he was actively seeking a solution of this staff problem to make it possible to use a certain number of emergency hospital beds for tuberculosis cases. A number of beds had recently been put at the disposal of the civil authorities.

Maternity Beds in London.—Dr. SUMMERSKILL asked on July 16 whether 200 expectant mothers were refused admission to Queen Charlotte's Hospital every month for lack of accommodation; and what action Mr. Brown proposed. Mr. Brown said substantial numbers of mothers who made inquiries at this hospital had to be refused admission. The arrangement made to compensate for the shortage of maternity beds in London was by provision in the Emergency Maternity Homes established in safer areas for the purpose. Additional maternity beds were being opened in London as fast as adaptation could be carried through and trained staffs secured.

Notes in Brief

The Ministry of Health Standing Committee on Medical and Nutritional Problems, consisting in the main of medical and other officers of the Departments concerned, has, in the two years of its existence, met seventeen times. It has given advice to the Departments concerned on a large number of problems submitted to it.

The estimated numbers of wholesale producers and producer-retailers of milk of tuberculin-tested and attested standard on June 1, 1943, were 2,280 and 1,030 respectively. The corresponding figures for June 1, 1942, were 2,190 and 1,110.

The regulations of the national milk and vitamins schemes have now been adjusted to allow widows and children of Service men to continue to receive free milk and vitamins where they were receiving these commodities free of cost before the death of the husband or father, provided that the normal weekly income from all sources remains unaltered except by the substitution of a pension for the Service allowance. The concession will be extended to widows and children of men who were not Service men where the circumstances are parallel.

The county medical officer of health has informed Mr. Brown that at the end of 1942 the numbers of immunized children in the county districts of Northamptonshire were 8,000 children under 5 and 28,250 children under 15. He pointed out that these figures represent 46 and 74% respectively of the population in the two age groups specified. This information was obtained as the result of a special investigation made by the county medical officer of health. According to information received from the county medical officer of health, 102 children under 15 in the county districts of Northamptonshire were notified as suffering from diphtheria in the period Jan., 1941, to Dec., 1942.

A note on the possible danger from carbon monoxide has been sent recently to every operator of public service vehicles driven by producer-gas. The danger is also explained in the "Manual of Instructions" which will be distributed with each producer-gas unit allocated to operators of goods vehicles.

Arrangements are being made to afford the British Hospitals Contributory Schemes Association an opportunity of expressing its wishes as to the changes in the present conditions of medical service foreshadowed by the Government's acceptance in principle of Assumption B of the Beveridge report.

Mr. Eden said on June 30 that there existed already in this country a Standing Committee on Nutrition, composed of representatives of various Government Departments and scientific bodies, which performed all the functions recommended in this connexion at Hot Springs.

The British Government has agreed to make a further grant-in-aid of £30,000 for the maintenance of medical and surgical teams for work among Chinese troops and civilians in the war zones of China in co-operation with the Chinese Red Cross and the Chinese medical services. The grant on this occasion will be made direct to the Friends' Ambulance Unit.

An antimalarial unit is operating at Mauritius at present, and an engineer is shortly being sent to Mauritius at the Governor's request to prepare, in conjunction with the local authorities, long-range plans for reducing the incidence of malaria. A nutrition unit is also working in the island, and plans for further extension of its activities are awaited.

The Services

Surg. Lieut. D. M. Sheppard and Temp. Surg. Lieut. A. S. Duncan, R.N.V.R., have been awarded the D.S.C. for resolution, enterprise, and fine leadership in a successful encounter with enemy Forces in the Mediterranean.

CASUALTIES IN THE MEDICAL SERVICES

Killed on Active Service in Middle East in July, 1943.—Capt. A. F. Smith, R.A.M.C.

DEATHS IN THE SERVICES

Lieut.-Col. GEORGE M'PHERSON, C.I.E., I.M.S. (ret.), died on July 15 in Switzerland, aged 70. After taking an Arts degree in Glasgow he proceeded to qualify with the M.B., C.M. of the same university in 1895, and he entered the Indian Medical Service in January, 1898. He soon saw active service in China in 1900-2 and in the Aden Hinterland. In 1905 he joined the civil medical department of the Bombay Presidency, where he was in charge of plague measures. In 1911 he took the F.R.C.S.E.d. and was appointed professor of ophthalmology in the Grant Medical College of Bombay. In the war of 1914-18 he was consulting ophthalmic surgeon to the Expeditionary Forces in Mesopotamia and was awarded the C.I.E. for his services in 1918. In 1926 he retired and afterwards lived in Switzerland, in Bellaria, Vevey, and Montreux, where his readiness to help in any difficulties was much appreciated. On the outbreak of the present war he volunteered his services in any capacity, but his age precluded his further military employment. His wife, the daughter of the late John Reynolds of Bristol, survives him, as does his elder brother, Sir Hugh M'Pherson, K.C.I.E., of the Indian Civil Service, who formerly served in Bengal.

Medical News

At the opening of the new academic session at Westminster Hospital Medical School the inaugural address will be delivered by the Right Hon. Ernest Brown, Minister of Health, on Monday, Oct. 4, at 3 p.m. Tea will be served in the school.

The Chadwick Trustees are offering three prizes—one of £100, one of £50, and one of £25 (accompanied, if the Trustees so decide, by a Chadwick medal or medals)—for the best three essays, received before Sept. 1 next, on architectural, engineering, and administrative principles (relative to sanitation and hygiene) which should be observed in the replanning arrangements of war-devastated towns or areas. Information in regard to the scope of the essays, etc., can be obtained by sending a stamped and addressed envelope to the Clerk to the Chadwick Trustees, 204, Abbey House, Westminster, S.W.1.

The Board of Directors of the Finney-Howell Research Foundation has awarded two new fellowships and has renewed three others for research into the aetiology and treatment of cancer. Fellowships, carrying an annual stipend of £2,000, are awarded for one year with the possibility of renewal up to three years. Applications must be made on forms obtainable from The Secretary, 1211, Cathedral Street, Baltimore, Maryland, and must reach the Foundation before Jan. 1 of each year. The appointments will be made in March.

Industrial workers are themselves taking an active interest in measures to promote safety and health, and in some factories health committees have been set up. Where no medical officer is available, however, it is difficult for them to obtain professional and technical advice, and the Leicester Branch of the Socialist Medical Association has been responsible for establishing a local Industrial Health Advisory Council, through which it is hoped that specialist advice on industrial health matters will be available wherever it is required. It is suggested that similar councils might be set up in other areas.

Arrangements have been made between the Ministry of Labour and National Service and the Ministry of Health under which State-registered nurses who on account of disability are not fit to return to their previous nursing work, but who are suitable for employment as sister tutors, health visitors, or industrial nurses, may receive training for that purpose.

Dr. John Robert Kennedy of Dunbeath, who graduated at Aberdeen in 1893 and has practised at Latheron for the past 44 years, has received a presentation from patients and friends to commemorate his jubilee in the medical profession.

EPIDEMIOLOGY SECTION

The King has commanded that the new general hospital under construction by the County Borough Council of Gateshead shall be known as the Queen Elizabeth Hospital. The original plan provided for 220 beds, with a maternity unit of 25 beds. During the war the full plan has been somewhat modified, and the buildings will probably provide altogether some 200 beds. It is expected that the maternity unit will open within the next two months and the general ward accommodation will probably be functioning about the end of the year.

The British Red Cross Society, in its report for the year 1942, announces its willingness to undertake the organization of a national blood transfusion service to come into operation with the end of the war. A number of conferences have been held, one of them attended by representatives of the civil and fighting Services, to prepare the basis for this national organization.

The bequests of the late Mr. R. W. T. Walker of Stirling include (subject to his wife's life interest) £4,000 to the Royal Faculty of Physicians and Surgeons, Glasgow, for further research into rheumatism; £4,000 to the Glasgow Royal Cancer Hospital for research; and £2,500 to Stirling Royal Infirmary if still maintained upon the voluntary principle.

During the past three years there has been an increase in the notification of tuberculosis in Sweden. Swedish health authorities are attempting to check this increase with the help of x rays and by vaccinating with B.C.G. In April-June this year, for example, 85,000 officers and soldiers of the Swedish defence forces were x-rayed. A special attempt is being made to examine in this way the population in the northern parts of the country, where tuberculosis is rife. Ultimately it is hoped to subject the whole population to x-ray examination by using screen photography.

The Association of Certificated Blind Masseurs received the following message from Viscount Dawson of Penn on the occasion of its annual general meeting: "I am delighted to hear such good accounts of the work of the Association and that the demand for the services of blind chartered masseurs and masseuses is so great. It is a tribute to the work the Association is doing, and doing so well." New members of the Association include civilians blinded in air raids during the present war and soldiers and sailors blinded in action.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In England and Wales the chief features of the returns were rises in the number of cases of scarlet fever by 123, and of dysentery by 67, and falls in the incidence of measles by 539, of whooping-cough by 174, and of acute pneumonia by 45.

With the exception of London and the south-western counties he fall in the incidence of whooping-cough was general, specially in Lancashire and Durham with 45 and 33 fewer cases than in the previous week. The increase in scarlet fever was due to the two counties of Lancashire and London, where notifications went up by 66 and 64. Measles continued to fall in most areas, especially in Lancashire 125, and Kent 69; but in Monmouthshire there were 106 more cases.

The notifications of dysentery went up from 93 to 160 during the week. The larger part of this rise was due to an outbreak in Kent, Eastry R.D., 49 persons being infected. Other centres of infection were Buckinghamshire 14, Amersham R.D. 8, and Salisbury R.D. 6; Caernarvonshire 14—from five administrative areas.

In Scotland a fall was recorded in the notifications of measles by 48, acute primary pneumonia by 50, whooping-cough by 20, scarlet fever by 18. Notifications of measles have dropped to about one-tenth of the level of five weeks ago, and during the present week 39 of the total of 49 were recorded in the two cities of Glasgow 22, and Edinburgh 17. The incidence of diphtheria rose slightly by 13 cases, over one-third of the cases being recorded in Glasgow. The most notable feature of the returns as the increase in notifications of dysentery from 64 to 125. In West Lothian County there was an outbreak of 39 cases, the other principal centres of infection being the cities of Aberdeen, Glasgow, and Edinburgh, with 18, 15, and 12 cases respectively. In Eire 14 cases of diphtheria in Donegal, Inishowen R.D., accounted mainly for the increase of 17 in the incidence of this disease. Of the 32 cases of whooping-cough 18 were reported from Kerry, Caherciveen R.D.

The Week Ending July 24

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 2,099, whooping-cough 2,081, diphtheria 591, measles 2,486, acute pneumonia 445, cerebrospinal fever 44, dysentery 105, paratyphoid 9, typhoid 10.

INFECTIOUS DISEASES AND

We print below a summary of Infectious Diseases Statistics in the British Isles during the corresponding week last year, for: (a) England and London (administrative county). (c) Scotland. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded are for: (a) The 126 great towns in England and Wales (administrative county). (c) The 16 principal towns in Eire. (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases; a blank space denotes no return available.

Disease	1943				
	(a)	(b)	(c)	(d)	(e)

Deaths (excluding still-births) Annual death rate (per 1,000 persons living)	3,790	492	517	164	130
Live births Annual rate per 1,000 persons living	6,502	782	938	398	272
Stillbirths Rate per 1,000 total births (including stillborn)	207	27	26	—	—

* Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

† Includes puerperal fever for England and Wales.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1.

ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Secretary of the Journal Board, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be sent to the Secretary.

TELEPHONE No.—B.M.A. and B.M.J.: EUSTON 2111.

TELEGRAPHIC ADDRESSES—EDITOR, Antiology Westcent, London; SECRETARY, Medisera Westcent, London.

B.M.A. SCOTTISH OFFICE: 7, Drumheugh Gardens, Edinburgh.

ANY QUESTIONS?

Complete Heart-block

Q.—A well-built man of 65 a year ago had a typical Adams-Stokes syndrome, and since then complete heart-block with a regular pulse at 30 to 34 per minute. The blood pressure ranges from 245/95 to 220/90. The arteries are soft, the urine and blood urea normal, and the Wassermann reaction negative. The heart is enlarged; there are no murmurs, and the veins at the root of the neck can be seen to pulsate at double the rate of the radial pulse. He has a mild hypnotic overnight. I have tried various drugs without much effect in relief of his symptoms, which are easy fatigability, shortness of breath on going upstairs, and general slowing down of activity. There is occasional slight oedema of the ankles. Is there any chance that the heart-block may disappear, and what can be done to further this? What other steps can be taken to make the patient comfortable and to prolong his life? The picture is slightly complicated by the fact that for some years he has had asthma and emphysema, the former now much less troublesome.

A.—This man is fortunate in having no recurrence of the Stokes-Adams attacks of a year ago. It used to be thought that when the block became complete the risk of further syncopal attacks was removed. That view was incorrect, though there is probably less likelihood of further attacks when the block has become complete. The systolic blood pressure is usually raised, and one need not regard him as suffering from hypertension in addition to the block. Some cardiac enlargement is also the rule. Further, he should expect to be more short of breath than those without heart-block; the other symptoms are perhaps referable in part to his age. The heart-block will persist and nothing can be done to rid him of it. As the Wassermann reaction is negative, and arteriosclerosis is the usual cause, no specific treatment will benefit him. He may be reassured as to his progress. The risk of recurrence of Stokes-Adams attacks is relatively slight, and the other ultimate risk is that of heart failure. It would only be if his dyspnoea became pronounced that this question of failure need be raised, especially as he is emphysematous. The most useful course will be to persuade him to limit his activities according to his breathlessness.

Achalasia of the Cardia

Q.—I have heard there is some drug useful for achalasia of the cardia, and should like to know what this is. The patient I have is 15 years of age and has been dieted since she was quite young. She has taken a semi-solid diet and her height and weight are above normal. She has never required bougies. She is still sick at some meals, but on the whole she takes a fair amount of food.

A.—When it was believed that the dysphagia was due to cardiospasm, it was natural to treat it with antispasmodic drugs, such as nitrites, nitroglycerin, benzyl benzoate, etc. Recent pathological studies, however, support Hurst's theory that achalasia is primarily a disease of the myenteric plexus. There is no organic narrowing or thickened sphincter at the lower end of the oesophagus. With destruction of the plexus, sympathetic fibres to the terminal portion of the oesophagus act without opposition, the terminal portion does not relax normally with the swallowing reflex, and dysphagia results. It has been suggested that the degeneration of the ganglion cells in the myenteric plexus is due to avitaminosis B, and that the disease should be treated with large doses of vitamin B₁₂, 20 to 100 mg. daily, by mouth or parenterally. This treatment would require prolonged trial, as recovery of the ganglion cells would obviously be slow. Another rational form of therapeutics is to use prostigmine

to reinforce the action of the parasympathetic supply of the terminal portion of the oesophagus. Prostigmine may be given either by injection, for which purpose it is put up in 1-c.cm. ampoules, or by mouth in tablets containing 15 mg. It is an expensive drug, and it would therefore seem desirable to observe the effects on the x-ray screen. If an effect cannot be demonstrated with an adequate single dose it would seem useless to continue the drug. In conclusion, it may be noted that no convincing results have been reported with either of these forms of therapy.

Treatment of Schizophrenia

Q.—The treatments of schizophrenia at present in vogue seem to me to go to the extremes of producing convulsions on the one hand and continuous narcosis on the other. Is there any evidence to prove which of the two is preferable? And would it be possible to state briefly what is the rationale behind these two treatments? To the general practitioner asked to advise the relatives of patients the situation is slightly bewildering.

A.—There is no acceptable rationale of convulsion treatment; its justification is empirical, the theory that led to its adoption having been mistaken. The theory of narcosis is roughly one of the simplest possible rest for the nervous system as a whole. Continuous narcosis is not often effective in cutting short schizophrenic illnesses. Convulsion treatment, on the other hand, while it cuts a good many of them short, is accompanied by a considerable relapse rate, so that its ultimate value in the treatment of schizophrenia is still in question.

Sulphonamides in Virus Infections

Q.—Sulphonamides seem to be of use in lymphogranuloma venereum and trachoma. Are they of value in infections with the psittacosis viruses?

A.—Experiments in mice (Burnet) have given negative results, though some limited experiments with sulphapyridine (Bedson: unpublished) suggested that this drug was not altogether without effect on psittacosis in the mouse. Meyer and Eddie report that a human case of ornithosis did not respond to sulphathiazole, and the failure to respond to sulphonamide drugs is one of the criteria on which the diagnosis of atypical pneumonia is made. However, the American literature contains the report of one case of psittacosis which responded to sulphapyridine (Hinshaw, 1940), and there have been two cases at the London Hospital (unpublished) treated with this drug with apparent success. An open mind on this question should, therefore, be kept until these drugs have been given a more extended trial.

Urticaria

Q.—What are the chief causes of urticarial rashes, and what are the best forms of treatment? Is it possible that heavy chlorination of the water is responsible for prevalence in children? I have observed that removal of a child on holiday leads to disappearance of the rash.

A.—The chief causes of urticarial rashes are allergic responses to foods, drugs, foreign proteins, and toxins, and the reactions are partly or wholly conditioned by metabolic factors, which may be dietetic, endocrine, or nervous. The problem and its treatment require a whole chapter of a dermatological textbook and cannot adequately be dealt with here. Chlorinated water usually produces a follicular eruption of minute urticarial papules rather like the rash of rubella, but in my experience the eruption is not common. Several observers have reported that urticaria in children almost invariably clears up without treatment when a child leaves its home, and some evidence exists to the effect that dust in the bedrooms is the offending allergen. Antigens prepared from dust have been used with some success in the desensitization of young urticarial subjects, but at least equally good results can be obtained by attention to the metabolic factors above mentioned plus hydrarg. cum cret., alkaline aperients, and 2% of phenol in calamine lotion.

Strains of Diphtheria Bacilli

Q.—(a) Is a "mitis" strain of diphtheria bacillus by definition incapable of producing a membrane and symptoms in man? (b) Conversely, are all strains isolated from cases of clinical diphtheria "virulent" and not "mitis"? (c) If the answer to both questions is Yes, then only strains from symptomless carriers need be examined for virulence?

A.—(a) No. Mitis does cause clinical diphtheria and even severe or fatal diphtheria. McLeod (*J. Path. Bact.*, 1939, 48, 99) described 48 fatal cases of diphtheria, of which 11 were due to mitis infection. Shone (*ibid.*, p. 139) recorded 783 mitis infections, of which 197 were moderate and 105 severe; 2.4% of the mitis patients died. The complication rates for mitis-infected patients were laryngeal 8.5, tracheotomy 5.2, circulatory 3.7, paralysis 2.8, severe toxæmia 0.3. (b) No. Probably the questioner has confused two points. Bacteriologists using tellurite plates quickly identify the types

isolated, and as they have found that almost all gravis and inter-medius strains are virulent in animal test, they dispense with this test in routine work. Mitis strains from cases of frank diphtheria may or may not be virulent.

Prognosis of Subacute Combined Degeneration

Q.—How has the prognosis of subacute combined degeneration of the cord been affected since the introduction of liver therapy and desiccated stomach extracts?

A.—The development of the spinal-cord lesions of pernicious anaemia can be completely arrested by adequate treatment with liver or stomach. Adequate treatment implies receiving more liver than is necessary merely for the maintenance of a normal blood count, and in the early stages of treatment a full dose of liver extract—i.e., 4 c.cm.—should be injected intramuscularly three times a week. Later the number of injections may be reduced to one a week, but this should be maintained for two or three years and only then reduced to once every three weeks. Signs attributable to peripheral nerve involvement generally disappear within six months. Subjective improvement in strength and ability to get around may continue for two or three years, and occasionally objective evidence of spinal disease, such as an abnormal Babinski reflex, may disappear during his period. Little improvement can be expected after this time, with the important proviso that there is often a considerable hysterical overlay which may respond dramatically to appropriate andling.

Oestrogens at the Menopause

Q.—Oestrogens, natural or synthetic, are recommended for the relief of troublesome menopausal symptoms. I should be glad to know whether expert opinion is in favour of giving these substances as a routine to every woman who reaches the menopause. What is the optimum dosage, and how long should the drug be continued?

A.—Routine administration of oestrogens to all women of menopausal age is to be deprecated, because only about 20% of women experience menopausal or climacteric symptoms of such severity as to be troublesome. For these, synthetic oestrogens, such as stilboestrol or hexoestrol, should be given in as small a dose as possible. With 0.5 mg. twice or three times daily by mouth, and if the symptoms are not relieved increase cautiously until the dose is sufficient to reduce the number of "flushes" to an average of four twenty-four hours. The object of treatment is not to give complete relief but to moderate symptoms to a reasonable extent. It is rarely necessary to give more than 1 mg. three times daily. Having determined the dose necessary to give relief, maintain that dose for two to three weeks. Then gradually reduce it over a period of three to six months, using always the number of "flushes" as a guide. This very gradual and regular reduction is the essential feature of the treatment, as it allows the endocrine system and other bodily functions to accommodate themselves to the diminished ovarian activity. This should be explained to the patient in order to obtain her co-operation. Prolonged and heavy dosage to secure complete relief of symptoms is never justifiable, and symptoms will recur if the treatment is stopped suddenly.

Dressing for Clean Ulcer

Q.—Following treatment, a superficial abrasion that was septic has healed, and there now remains a shallow clean ulcer with a granular base. What dressing should be applied and how often should it be dressed? Some dressing is essential in Service patients on duty.

A.—The dressing should shield the ulcer from further contamination and injury, and this can be achieved most conveniently by covering the surface lightly with sulphanilamide, and then applying a few layers of gauze impregnated with sterile vaseline or a layer of tulle gras. This dressing may be held in place by a covering of elastoplast, and if the ulcer is not too large, and if movement of the part will not interfere with healing, the patient can remain at duty. The dressing should be left untouched for at least a week, and if still unhealed yet progressing satisfactorily, the procedure may be repeated for another week. If, however, healing is retarded, the part must be immobilized.

More about Earwigs

Q.—In reference to the answer to the question about earwigs (10), could you inform me (1) how to prepare dried apple juice, and (2) whether sodium fluoride is poisonous to cats or not?

A.—Apple pomace is a commodity sold as such. It is the flour left over from dried apple rings. Perhaps chicken balancer meal would be more readily available now as a substitute. Sodium fluoride is fairly poisonous to mammals: the median lethal dose is about 1/2 g. per kg. On the other hand it seems unlikely that domestic animals would lick up a sufficient quantity to be dangerous if the bait is spread in small crumbs suitable for rats.

INCOME TAX

Annuity Policy with the Medical Sickness, Annuity and Life Assurance Society

"R.N.V.R." pays £16 19s. a year on an annuity policy with the society, taken out under the B.M.A. pension scheme. He has claimed, but has not received, an allowance for the premiums.

* He should write to the Assessor of Income Tax, Admiralty, to the Chief Inspector of Taxes, the Hydro, Llandudno, requesting the allowance, and pointing out that the policy was taken out in connexion with the National Health Insurance Practitioners' Pension and Insurance Scheme.

Free Quarters in a State Institution

"M.D., M.S." holds an appointment in a State institution receiving a salary and free quarters. Is he liable to pay tax on the annual value of the quarters occupied by him?

* The legal rule is in No. VI of Schedule A, which provides for the exemption of the "tax charged on any hospital . . . or almshouse in respect of the public buildings . . . not occupied by any individual officer or the master thereof. . . ." This means that the quarters in question remain chargeable to tax, and "M.D., M.S." becomes liable for payment. It is of course possible that the amount at which the quarters are valued is excessive, or that there are some special circumstances of the particular case affecting the liability; we can only state here the general position.

LETTERS, NOTES, ETC.

Medical Directory, 1944

The Editor of the *Medical Directory* (104, Gloucester Place, Portman Square, London, W.1) writes: To maintain the accuracy of our annual volume we rely upon the return of our schedule, which has been posted to each member of the medical profession. Should the schedule have been lost or mislaid we will gladly forward a duplicate upon request. The full names of the doctor should be sent for identification.

Morton's Metatarsalgia

The author of our note (*Journal*, June 26, p. 808) under the above heading writes: It was obvious to me that the original inquiry came from a general practitioner who wanted straightforward guidance probably upon the very common condition frequently referred to by G.P.s as such, but which, as Mr. W. Sayle Creer rightly points out, is not quite the same thing as that originally described by Morton. On the other hand Mr. Sayle Creer has done nothing to clarify the position. On the contrary, he has told us that the Mortons were quite wrong in their interpretations of the eponym, which I still maintain is not a diagnosis; neither do I think that Mr. Sayle Creer knows what the "diagnosis" is. At any rate, he hasn't told us.

Salvage of Agar

Dr. H. H. GLEAVE writes from the Pathological Department, Royal South Hants and Southampton Hospital: In the *Journal*, July 3, p. 16, a reference is made to the recovery of agar. As agar is valuable salvage I asked Mr. R. White (my technician) to work out a method, and this has been in use here for the past year. We hope to publish details elsewhere, but briefly the method is as follows. A large flask with funnel is left in the steamer and the used agar dropped into the funnel and filtered. When the flask is full the agar is again filtered, dried in trays in the hot-air duct, washed for six days in a slow stream of water in an old charcoal type water filter, dried, and bottled. The yield is about 60%. Even on a small scale the recovery seems worth while.

Oedema of Extremities at Sea

Mr. VAUGHAN PENDRED (Tilford, Surrey) writes: The letter of Dr. Harold Thorn (June 5, p. 708) recalls to me a like experience of oedema of the legs at sea when I was a P. & O. surgeon 42 years ago. The chief officer, myself, and two passengers I recall with this alarming disfigurement of our lower limbs. The late Dr. J. H. Bryant of Guy's had reported oedema occurring in patients with tremendous salt appetites, and cure by deprivation. Now surely at sea the ideal conditions for excessive salt intake are present. The bow wave of a ship in fine weather is present day and night. In bad weather the waves break and the air is intensely laden with salt. One day on shore used to cure the oedema.

Interstitial Emphysema

Dr. G. H. DARLINGTON (Leeds) writes: It would appear that the occurrence of interstitial emphysema during labour is not so very infrequent. On June 11 of this year a patient of mine, a healthy primipara aged 26, developed the typical swelling of the neck, face, and right arm during a rather prolonged second stage. Curiously enough it started about one hour after I had given an injection of 1/4 gr. of morphine, when the patient was comfortable and not straining. The emphysema disappeared in about a week. The only point of interest in her past history is that at the age of 10 she was treated for tuberculous glands of the neck.

LONDON SATURDAY AUGUST 14 1943

EXPERIENCES IN MILITARY DERMATOLOGY*

BY

R. M. B. MacKENNA, M.A., M.D., F.R.C.P.

Brigadier; Consulting Dermatologist to the Army

So far as I have been able to ascertain, the best starting-point for this essay is July 23, 1903, for on that date the Advisory Board for Army Medical Services appointed a subcommittee of eminent men "to consider the question of the treatment of venereal diseases in the Army, and to inquire into the question of the treatment of itch." The chairman and the secretary of the subcommittee widened its terms of reference very considerably, and included in its purview "the arrangement and equipment of wards and hospitals for the treatment of certain" (unspecified) "skin diseases"; they summoned to its conferences most of the eminent British dermatologists of the day (including Radcliffe Crocker, Malcolm Morris, Jonathan Hutchinson, T. Colcott Fox, and Arthur Whitfield) and sent a representative to the leading civilian and military hospitals in France, Germany, Austria-Hungary, Italy, Russia, Sweden, Denmark, and Belgium. Eventually four large reports were published by His Majesty's Stationery Office,¹ and in the last of these, among many other recommendations, the subcommittee advised the segregation of skin cases in special sections of military hospitals, recommended that in these hospitals "in charge of sections for the treatment of venereal and skin diseases should be placed officers who have qualified as 'Specialists in Dermatology, including Venereal Diseases,'" and stated that it would be "of advantage to the service that junior officers intending to present themselves for examination in the subject of dermatology and venereal diseases when qualifying for promotion to major should be appointed to stations where wards for the treatment of these diseases exist under the charge of an officer with the 'Specialist' qualification."

It would have been reasonable to assume that with the backing of the subcommittee's findings and the blessing of the Advisory Board military dermatology would have forged ahead. But venereal maladies are a greater hazard than cutaneous diseases to a peacetime army of selected men, and the medical officer who desired to specialize in the latter found that, although nominally he was a dermatologist, the larger part of his clinical duties was the treatment of venereal disease.

In the South African War (1899-1902) skin diseases had been found to be one of the principal causes of inefficiency in the Army; during this campaign the average annual incidence of skin diseases per thousand troops was 23.71—i.e., approximately half the battle casualties. In the war of 1914-18 skin diseases again became notorious because of the inefficiency they caused. In 1915, in the United Kingdom, 40.88 men in every thousand were admitted to hospital because of diseases of the skin and areolar tissue; in France and Flanders in the same year the ratio was 126.13 in every thousand.² But despite the high incidence of skin diseases the dermatologists were singularly unsuccessful in leaving a permanent impression upon military administration. In the years of comparative

tranquillity between 1918 and 1939, for the reason given previously, dermatology in the Army again became a specialty in which venereology was predominant.

The Early Days of the War

Of the first nine months of the present war I shall say little. The dermatological work which was carried out during this period in the B.E.F. in France (1939-40) has been recorded by Colonel J. T. Ingram.³ For those of us who were on service in the United Kingdom it was probably the hardest and most difficult period to date. We who were working in England naturally and rightly did not have our indents for drugs and stores fulfilled until the B.E.F. were supplied. Not only were the shortages of drugs, syringes, etc., a matter of concern, but also we had many difficulties with personnel; for much of our time was spent in training men, many of whom had but little vocation for nursing, without assistance from sisters or from nursing orderlies. In the hospitals at home, no sooner had we trained a batch of men than they were swept away to other units, and the training of the next batch of raw recruits and inexperienced medical officers began. This difficulty with personnel has given us considerable trouble throughout the war. Much (but by no means all) of the work of a dermatologist in the Army must be done in military or general hospitals. It is the duty of the staffs of the former, and to a less degree of the staffs of the latter, to train personnel, and the shortage of man-power is such that it is very difficult to arrange for a cadre of N.C.O.s. trained nursing orderlies, or special treatment orderlies to remain in each hospital as a nucleus to assist in the training of each batch of newly enlisted men.

A New Establishment and a Policy

In Nov., 1941, largely as the result of the representations that were made by the Director of Hygiene (Major-Gen. D. T. Richardson) and Lieut.-Col. (now Brigadier) T. E. Osmond, R.A.M.C., and with the valuable support of members of the Consultants Committee, a new establishment was created in the Army Medical Department: Brigadier Osmond continued to be Adviser in Venereology, and I was appointed Adviser in Dermatology. It must be understood that the dermatologist who is War Office Adviser has not *carte blanche* to organize dermatology in the Army in accordance with his own fancies or the beliefs of his officers. It is his duty to weigh the merits of the policies he conceives or the proposals he receives, and then, if they involve major questions, so to marshal the facts and figures concerning these matters that he can present to higher authority a watertight and convincing case for their acceptance and adoption. Having received an acceptance in principle, he must then take the necessary steps to have the scheme implemented.

In Nov., 1941, my first duty was to formulate a comprehensive policy for dermatology in the Army. The following is an outline of this policy, so far as the work in the United Kingdom was concerned.

1. In each Command† there should be a Command Specialist in Dermatology: he should have the professional status of

* A paper read before the British Association of Dermatology and Syphilology on July 2, 1943.

† As is well known, for the purposes of military administration the United Kingdom is divided into several large Commands. For medical purposes the Command is the major administrative unit.

a consultant and should hold a higher diploma in medicine or surgery, but in a few cases in which ability in organization or in dermatology was recognized this academic standard might be waived.

2. So far as possible, military dermatology should be centralized in military hospitals.

3. Officers in medical charge of units should be instructed to send all difficult cases (without delay) to hospitals where dermatologists were available rather than to admit these cases to subsidiary medical centres where, because of lack of specialized knowledge or advice, the course of the disease might be prolonged.

(This item of policy, simple though it appears to be, was not put forward without much consideration; for it was a matter which affected the interests of many keen medical officers who would have preferred to keep these cases under their own care. But our criterion of therapy is that it must be carried out with the maximum speed compatible with efficiency, and it was obvious that the detailed knowledge of the specialist was more likely to ensure rapidity and efficiency than the efforts of a medical officer, however keen, who had no special knowledge of cutaneous diseases.)

4. Military dermatological centres should not be isolated units, but should be part of or attached to military or general hospitals.

5. The equipment—surgical, electrical, and pharmaceutical—should be of a standard comparable to that of the dermatological department of the average teaching hospital. In one centre in each command x-ray therapy should be available.

6. A scabies officer—a graded dermatologist—should be appointed in each Command.

A Memorandum embodying this policy was drafted; it contained, *inter alia*, reference to the dermatological education of medical officers, and reference to preventive dermatology and rehabilitation.

The justification for the policy submitted was that, if carried out, there would be a reduction in the loss of time and the wastage of man-power due to skin diseases, and certain economies in finance and material would be effected. All the proposals, except that for scabies officers—which was refused on the grounds of shortage of medical officers—were accepted in principle.

There followed visits to most military hospitals and many camp reception stations from the Moray Firth to Cornwall and from Londonderry to Canterbury. New establishments for a certain number of dermatologists had to be obtained; dermatologists had to be enlisted, passed through the depots, and posted to Commands. Additional bed accommodation had to be found. The details of the policy had to be explained in the Headquarters of Commands. Many E.M.S. hospitals were visited, and it is a pleasure to acknowledge my indebtedness to the executive and clinical officers of the E.M.S., who have always cordially smoothed my path.

In May, 1942, the Director-General E.M.S., having considered our plea for centralization of treatment, issued an Instruction directing that if a Service patient had been admitted to an E.M.S. hospital, and if cure had not resulted within three weeks from the date of admission, that patient should be transferred to one of the hospitals having special facilities for treating skin cases listed in Section XII of E.M.S. Instructions, Part I.⁶

Besides these administrative matters, items of clinical interest were dealt with. Two pamphlets—"Notes on the Prevention and Treatment of Scabies, 1942," and "Memorandum on Cutaneous Diseases, 1942"—were written, and published by command of the Army Council.

Implementing the Policy

In July, 1942, an order was promulgated implementing the first item of the policy outlined above: Command Specialists in Dermatology were nominated for all Commands in the United Kingdom, and their duties and responsibilities were defined as follows:

1. The Command Dermatologist is the adviser of the Deputy-Director of Medical Services of the Command in all matters concerning the prevention and treatment of skin diseases.

2. He is responsible for the treatment of skin diseases in the hospital to which he has been posted.

3. He is to visit, periodically, all military stations in the Command where skin diseases are treated and to report to the D.D.M.S. concerning the efficiency of these stations. (When properly carried out visits are among the most valuable services which he renders.)

4. He is to advise and train medical officers in the principles of diagnosis and treatment of skin diseases. (In many skin centres teaching rounds are undertaken in the wards.) He is responsible for the training of orderlies and V.A.D.s.

5. He is to maintain cordial liaison with those E.M.S. hospitals where military dermatologists attend in a consultative capacity.

6. He has authority to delegate certain of his duties.

It will be seen from this schedule that the Command Specialist has heavy responsibilities. He is both the pivot and the mainspring of the system in the Commands. Once in every three or four months there is a Conference of Command Specialists in Dermatology at the War Office.

Grading

Thus far reference has been made to Advisers and Command Dermatologists without describing the hierarchy of dermatology in the Army; this omission must now be rectified. Besides Command Specialists and Advisers there are Specialists and Graded Specialists in Dermatology; also we have a few carefully chosen officers who are being trained in the specialty.

It may be of interest to specify the standards required of those who wish to be posted as "Graded Dermatologists" and "Specialists in Dermatology." A "Graded Specialist" should be in possession of higher medical qualifications. He should have been qualified in medicine for three years and employed in his specialty for at least one year. A "Specialist" must have the same qualifications as the "Graded Specialist," but with at least three more years' experience in his specialty; his age should be 32 years or over. Because of the pressure of the years we have had to reduce our standards, but the reduction has only been slight.

There is a general belief that military dermatology is a simple business. Certainly dermatology in the Army is simplified by two factors: first, we deal with persons of a selected age group; and, secondly, we deal with men and women who have been passed for service after a medical examination. But as the age limits widen and as, under the exigencies of war, the standards of physical fitness are relaxed, the scope of dermatology (as of other branches of medicine) widens proportionately, and we see a number of cases of unusual interest and difficulty.

Nursing

There is one important matter to which reference must be made, and that is to the assistance which the Matron-in-Chief, Q.A.I.M.N.S., Dame Katharine Jones, has readily given us on every occasion when we have sought her help. She, who once worked with Dr. H. G. Adamson, is anxious that every facility should be given for skin cases. On April 29, 1942, she signed a Memorandum on behalf of the Director-General, Army Medical Services, stating that matrons and sisters in charge should particularly interest themselves in skin wards, and whenever possible a sister should be posted to supervise the treatment of skin cases, "which should be regarded as an important branch of nursing duties." Since the issue of that Memorandum developments have occurred, and it is hoped that soon new establishments will be promulgated whereby sisters will be available to supervise nursing in the skin wards of all military hospitals. Dame Katharine is anxious that one of the good results of this war will be that in future the British soldier when suffering from skin diseases will be nursed in wards supervised by sisters.

Thus, briefly, are summarized the most salient advances in military dermatology which have occurred at home in recent months. There has been much else. We have recently launched a scheme on a small scale for the rehabilitation of men who have suffered from certain cutaneous diseases. This scheme, though no longer in embryo, is still in swaddling-clothes, and therefore will be mentioned without comment.

With regard to the Forces abroad, an adviser in Dermatology has been posted to the Persia-Iraq Force and another is serving in the Middle East. I have no intention of widening the scope of my remarks by reviewing the work of dermatologists in India, Persia, and Iraq, in Palestine, in Egypt and Libya, in North Africa, and in more remote parts of the globe: our colleagues will tell their own histories when they return, and theirs will be records of high endeavour and

success. It has been interesting to see how each dermatologist who has been commissioned has seized upon one particular facet of dermatology as being particularly his, and by disseminating his special learning has contributed greatly to our common knowledge.

Some Contributions of Note

Many clinical investigations and field trials have been undertaken: some contributions of value have been published in the medical press. Our observations have ranged from the bullous striate dermatitis which occasionally develops on those who lie down in green pastures, to methods of using "plastics" in the service of dermatology. Reference to the work (published or unpublished) of individual officers would be invidious, but as Major G. A. Hodgson's observations⁷ on the incidence of scabies and its apparent dependence upon the incidence of subnormal intelligence have been criticized, I wish to make the following comment. From my own observations I believed that Major Hodgson was correct in his general view that the incidence of scabies was greater in troops of low mentality than in individuals more favoured mentally; but because of Hodgson's use of norms derived from R.A.M.C. recruits, it is possible that the figures obtained in this group were too high and consequently the number of cases which appeared to fall in the lowest intelligence group were exaggerated. The figures (see Table) supplied by Lieut.-Col. G. R. Hargreaves,

Table showing Proportion of Scabietic Recruits of Different Intelligence Levels

Intelligence Grading	Scabietic Recruits	Strength of Intakes by S.G.s	Ratio
S.G. 1	21	3,945	0.5%
S.G. 2	65	6,983	0.9%
S.G. 3	109	9,389	1.2%
S.G. 4	89	8,246	1.1%
S.G. 5	123	6,565	1.9%
S.G. 6	46	2,102	2.2%
	453	37,330	1.1%

R.A.M.C., after an investigation of the incidence of scabies in approximately 40,000 recruits suggest that while Hodgson's figures are an over-estimate of the relation between scabies and low intelligence, nevertheless a positive significant relationship does exist, particularly in the very lowest intelligence group.

But, besides this flight into the *terra incognita* of psychosomatic tendencies, we have done much work on scabies, and we are proud of the enormous saving in transport, material, and finance which has resulted from the introduction of the treatment of scabies in units without segregation of the patients. From the administrative point of view it was a bold step for the Director of Hygiene to sanction this innovation, for had it not been successful the incidence of skin diseases would have soared; but, thanks to the careful work of unit medical officers, hygiene officers, and dermatologists, this innovation has been a success, and not only has there been a great saving in the material matters just mentioned, but there has also been much economy in that even more valuable factor, time.

All too often it has happened that the experiences gained in war have been forgotten in peace, and, before I conclude, there are some matters to which I must refer.

General Standard of Dermatology

In the Army not only is there a cross-section of the population—there is also a very fair sample of the graduates who have emerged from all the medical schools in the United Kingdom during the last 20 years; one is thus afforded a unique opportunity of assessing the general standard of medical knowledge attained by these men and women. In the Official History of the last war⁸ it was stated that:

"The outstanding feature of this statistical review of diseases of the war . . . is the large number of men rendered ineffective by the simple ailments of everyday life, such as diseases of the respiratory and digestive systems, rheumatic fever and its allied conditions, local and general injuries, skin diseases, minor septic infections, and influenza. These disabilities . . . form the bulk of the illnesses suffered by the seven million insured people who apply for medical treatment every year. . . . The medical services both of the Army

and of the civil population have here a common enemy and a common objective. Herein lies scope for research, rich in opportunity during peace, full of possibility for the future, and well worth constant investigation if preventive medicine is to reduce the admission rate to hospital at home and abroad, in peace and in war."

Without presuming to comment on the standards of medical education in any subject but that of our specialty, I feel it my duty to state that, in my opinion, the standard of dermatological knowledge of recently qualified medical men is not proportionate, as it should be, to the incidence of cutaneous diseases in both civil and military practice. It is not only the recently qualified medical men whose knowledge of cutaneous diseases could be improved with benefit to the community. The standard of many of their senior colleagues also leaves much to be desired. One can substantiate these statements in many ways: for example, Major K. Mellanby, R.A.M.C., has reported that in a sample of 1,000 successive cases sent for treatment to a scabies clinic 280 were not suffering from scabies. I do not accept this figure as having a general application throughout the Army, but I do agree with the implication of the statement—viz., that the error in the diagnosis of cutaneous diseases in general and of scabies in particular is much higher than it should be.

Both in war and in peace the loss of man-power days and working hours, the wastage (by misapplication) of drugs, and the amount of human misery caused by "trial and error" therapy based on uncertain diagnosis, are matters which should give the greatest concern to those responsible for planning medical education. These matters are not new; in 1904 Malcolm Morris⁹ made the same plea for accuracy in elementary dermatological diagnosis. He referred particularly to the cases of dermatitis herpetiformis which he had seen and which previously had been repeatedly diagnosed and treated as scabies. That pitfall is still a successful trap to most medical officers to-day, and I submit that there is something fundamentally wrong in a system of education against which an indictment couched 40 years ago can justly be made.

It is worth considering whether or not the teaching of the acute infectious fevers should be linked more closely with the teaching of dermatology, for in many of these fevers the diagnosis is primarily made on the appearance of an eruption, and the clinician makes his diagnosis by paths of thought and trends of observation which are particularly dermatological. I do not advocate that we should incorporate in our specialty the treatment of infectious diseases. All I suggest is that, in teaching, there should be a closer liaison than at present exists between the expert in fevers and the expert in skin diseases. By this means the standards in both these specialties would be raised.

The quotation⁸ given earlier from the Official History of the last war concerning the relevant incidence of diseases both in war and in peace confirms, to some degree, my disbelief in the story that skin diseases are statistically predominant only in war. I doubt very much if the proportional incidence of, for example, respiratory and cutaneous diseases differs greatly in war and in peace. My contention is that skin diseases are statistically and economically of great importance in peace; but the facilities for their treatment are relatively limited even in many of our larger cities, and the public rely to such a degree on patent medicines, preparations obtained from quacks, or self-prescribed remedies purchased from chemists that an enormous number of cases of skin disease are never seen by the medical profession. It may be said that this does not matter—that the majority of people are eventually cured by these methods. Even if this very debatable statement is accepted as true, it does matter, because we are squandering our pharmaceutical resources in making tons of remedies each year, many hundredweights of which are misapplied or wastefully used; further, by faulty treatment the period of cure is prolonged, working hours are lost, and diseases are disseminated.

The traditional system of treating the majority of skin patients as out-patients can be, and often is, incredibly wasteful in drugs and dressings; it can also be inefficient and time-consuming. I believe that a statistical survey would indicate that at least 5% of the available hospital beds in the country should be earmarked in peace for dermatology, and it may well be that a higher percentage than this is really necessary.

The Advancement of Dermatology

With regard to the specialty itself, and to those who practise it, the lack of a Diploma in Dermatology is a serious handicap to the advancement of the subject. Holders of special diplomas are essentially men whose competence has been assessed by others than their own teachers. Even allowing for the faults inherent in an examination system, one usually finds that the majority of men who have achieved a difficult diploma are men of worth. In these highly competitive days when most specialties in medicine and surgery have their diplomas, there is considerable danger lest the poorer quality of man is attracted to a specialty which demands no particular hall-mark of intensive effort. The establishment of a diploma would not benefit only the diplomates—it would tend to standardize, and thus to improve, the nomenclature of our subject, to crystallize our views on therapy, and very materially to increase the standards of teaching of dermatology.

It is desirable that we should develop much greater facilities than at present exist for research. At the present time, when the methods of research are becoming more and more specialized and the technicalities of mathematical assessment are becoming increasingly important, there is danger lest we be outstripped in research in our own specialty by scientists who have had little or no dermatological training. There are problems of preventive dermatology which must be solved—problems in rehabilitation which must be met. In these fields we can make rapid progress, particularly if we collaborate with our colleagues in physical medicine, pharmacology, chemistry, and psychology.

Points Relevant to the Army

Finally there are three points relevant to the Army to which I must refer. When the time comes for us to shed the bright panoply of war the measure of our success—or failure—in our present effort will be the effect which our work has had in influencing the military medical strategy of the future. Very sincerely do we hope that we will have succeeded in ensuring three matters:

1. That in times of peace dermatology is not swamped by venereology, and that a permanent cadre, small though it will be, of medical officers will keep alight the torch of dermatology.

2. That from the outset of any future campaign it will be remembered that skin diseases are a vital cause of inefficiency and that full provision will be made both at home and abroad for dermatological services, proportionate in size and efficiency to the problems which will assuredly arise.

3. That, with the help of the Matron-in-Chief, the British soldier suffering from a cutaneous disease receives treatment in wards in which the nursing is supervised by sisters.

We, the dermatologists in the Army, owe much to many officers of high and low rank who have helped to smooth our way; it would be an impossible task to name them all, as one would like to do; but to three officers of the higher executive we are greatly indebted—first, to the Director-General, Army Medical Services (Lieut.-Gen. Sir Alexander Hood), who has always appreciated the significance of our work, and done much both at home and abroad to ensure that our contribution to the war effort was utilized to the full; secondly, to the Director of Hygiene, Major-Gen. D. T. Richardson, who has given daily attention to our problems, and on whose staff I had the honour to serve; and, thirdly, to the Consultant in Venereology (Brigadier T. E. Osmond), who, with General Richardson, was largely responsible for ensuring that dermatology and venereology went their separate but harmonious ways, and that we too had the full recognition of War Office representation.

PEPSIN INACTIVATION IN ULCER THERAPY

BY

A. MORTON GILL, M.D., M.R.C.P.

Research Assistant in Department of Physiology and Courtauld Research Ward, Middlesex Hospital

AND

C. A. KEELE, M.D., M.R.C.P.

Lecturer in Pharmacology, Middlesex Hospital Medical School

The treatment of peptic ulcer is largely based on methods designed to neutralize the free HCl of gastric juice, so it is important to understand, first, what degree of neutralization is required, and, secondly, how successful modern treatment is in achieving this end. Neutralization is commonly thought to mean complete neutralization to pH 7, but in practice this is very difficult to produce, and dangerous owing to the considerable risk of alkalosis.

In order to understand the purpose of neutralization of gastric free acid it must be realized that its chief function is to create the required medium for the action of the proteolytic enzyme pepsin, which initiates digestion of proteins. The activity of pepsin is greatest at pH 1-2—the value in pure gastric juice—and this activity is abolished probably at pH 3.5 and certainly at pH 5 (Hollander, 1939). Now the normal gastric mucosa is resistant to digestion by its own gastric juice, but an ulcerated gastric mucosa, and probably also the intact mucosa of the small intestine, are susceptible to peptic digestion when the required pH is present, as has often been demonstrated in experimental work on ulcer production. This has recently been well shown by Schiffrin and Warren (1942), who perfused loops of cat's small intestine (including duodenum) for 12 hours with N/10 HCl, which damaged the mucosa very little, but when pepsin was added to the perfusing fluid extensive ulceration, bleeding, and perforations of the gut were seen. It was further shown that at pH 2.24 pepsin had no such effects and that the maximum destruction occurred at pH 1.10. Similar effects on the gastric mucosa were obtained in chronic experiments when the stomach was perfused through a fistula. From these experiments in cats it is seen that even N/10 HCl has little harmful action *per se*, and that relatively slight neutralization is necessary to reduce peptic activity. There is certainly no evidence to show that a pH of 3-4 is by itself capable of damaging an intact or ulcerated mucosa in animals or man, and pH values of over 4 would appear to be unnecessary in counteracting the activity of pepsin.

The common method of measuring the acidity of gastric juice is to determine the volume of N/10 NaOH required to neutralize 100 c.cm. of gastric contents, using Toepfer's reagent, which changes colour at pH 3-4, to measure "free acid," and phenolphthalein, which becomes coloured at pH 8-10, to measure "total acid"; other indicators are occasionally employed. Toepfer's reagent is not very accurate with opaque fluids, but it does indicate a pH change at about the desired value, and the pH of the sample can be roughly estimated from the amount of N/10 NaOH required to change the colour. If the sample does not give a red colour to Toepfer's reagent it may be assumed that peptic activity is negligible. Total acid values give no useful information.

pH values of gastric contents have also been studied by electrometric determinations on samples aspirated from the stomach—a much more accurate technique than the indicator methods; and recently the preparation of electrodes suitable for direct insertion into the stomach has provided a method for continuous recording of pH *in situ*.

Our purpose in this paper is to emphasize that inactivation of pepsin is the aim of peptic ulcer therapy and that this is obtained by neutralization to pH 3.5-4, and we shall consider how effective the usual method of treatment by milk and antacids is in fulfilling this aim.

Effects of Milk on Free HCl in Gastric Juice

Milk is the basis of the dietetic treatment of peptic ulcer, so its actions are very important. Freezer, Gibson, and Matthews (1928) showed that milk can neutralize an equal

volume of 0.3% HCl to pH 4, so the amount of milk in an ulcer diet would theoretically deal with the total quantity of acid secreted daily, provided the milk is given at the right times. Hurst (1928) noted that milk neutralized more effectively than carbohydrate feeds, and that hourly feeds were more effective than two-hourly. We have made observations on ulcer patients in whom a Ryle's tube, introduced via the nose,

Fig. 1.—Patient No. 1: 10 oz. of milk two-hourly.

Fig. 2.—Patient No. 2: 10 oz. of milk two-hourly.

Fig. 3.—Patient No. 3: 10 oz. of milk two-hourly.

Fig. 4.—Patient No. 1: 10 oz. of milk hourly.

Fig. 5.—Patient No. 1: Continuous-drip milk.

was retained for several days, and samples of gastric contents were removed hourly, day and night, just before a feed. Free acid values were determined, using Toepfer's reagent as indicator.

10 oz. of Milk Two-hourly.—There are considerable individual variations in response to milk, and Figs. 1, 2, and 3 show free acid values in 3 patients with gastric ulcer, which radiographs and gastroscopy showed to be of similar size and location, when 10 oz. of milk was given two-hourly.

10 oz. of Milk Hourly.—The patient whose response to 10 oz. of milk two-hourly is shown in Fig. 1 showed complete neutralization of free HCl on hourly feeds of 10 oz. of milk (Fig. 4). Other patients have shown proportional reductions of free acid levels.

Continuous-drip Milk (6 Pints in 24 Hours).—This method of administration was introduced by Winkelstein (1933), and has the great advantage of being effective by night as well as by day. Fig. 5 illustrates this point in the same patient as above. The obvious disadvantage of this procedure is the continuous presence of the tube in the stomach, but we have found that if the tube is passed intranasally and removed every other day for cleaning the discomfort is reduced to a minimum. Breuhaus and Eyerly (1941) found that 3 oz. of milk half-hourly raised the pH to 2.4-2.9 and was superior to magnesium trisilicate, $\text{Al}(\text{OH})_3$, and NaHCO_3 , given in doses which were roughly equal to milk in neutralizing capacity *in vitro*. Cornell, Hollander, and Winkelstein (1942) have shown that a continuous NaHCO_3 -milk drip keeps the pH of gastric contents about 4 (control pH 1.2-1.5) and is somewhat better than continuous $\text{Al}(\text{OH})_3$ drip, which produces a pH of about 3.5. Wosika (1938) has suggested that powdered skimmed-milk tablets are more effective than liquid milk or cream.

Mode of Neutralizing Action of Milk

Milk contains several substances which may influence gastric secretion. The fat is probably the most powerful constituent, and its inhibitory effect on gastric secretion has been frequently confirmed since the original observations of Ewald and Boas (1886). Fat inhibits gastric movements and secretion when it reaches the duodenum, and fatty acids are far more active than the fats from which they are derived (Card, 1941). It has been demonstrated by Ivy (1937) that the action of fats is due to the liberation in the intestinal mucosa of a substance called enterogastrone, which in turn inhibits the movements and secretion of the stomach. Sugars in high concentrations also inhibit gastric secretion and mobility, and it has been shown by Day and Komarov (1939) that glucose acts partly after absorption by a central action due to the rise of blood sugar, and partly by a peripheral, probably osmotic, action. We have found that glucose, cane sugar, and lactose inhibit gastric secretion in man, but the effective concentration of the last-named is about 12.5% as against the 4% present in milk, so it is unlikely that the neutralizing action of milk owes much to its lactose content.

Proteins of course act as buffering agents, but some proteins can stimulate gastric secretion, probably through their breakdown products. We found that 20 g. of egg albumen hourly greatly increased free acid secretion in man, but Matzner, Windwer, Gavron, and Sobel (1941) showed that gelatin reduced the free acid response to histamine. Levy and Siler (1942) have found that a solution of amino-acids obtained by hydrolysis of casein (amigen) maintained the pH of gastric contents above 3.5 for half an hour after oral administration to normal subjects. The calcium present in milk will also neutralize free HCl.

Thus the inhibitory effect of milk is due partly to depression of secretion and partly to neutralization, and if given in quantities greater than 5 oz. hourly milk is undoubtedly an efficient therapeutic neutralizing agent; but in most cases something more will be required to raise the pH to 4, so antacids must now be considered.

Gastric Antacids

Antacids are almost invariably used to supplement the neutralizing action of milk. Their efficiency has been tested by measuring their neutralization of free HCl *in vitro*, but more useful information can be obtained by studying the reaction of gastric contents after oral administration of antacids. Direct electrometric measurements of pH are more informative than indicator studies, and have been used by Kirsner and Palmer (1940) and Breuhaus and Eyerly (1941) on aspirated samples of gastric contents, and by Flexner and Kniazuk (1941) and Breuhaus and Eyerly (1941) in the study of gastric pH *in situ*, in the dog and man respectively. In this way all grades of neutralization may be accurately measured, and continuous recording is possible with the electrodes in the stomach.

Kirsner and Palmer (1940) and Kirsner (1941) recorded the pH of aspirated gastric samples at hourly intervals in patients with healing duodenal ulcer who were given hourly feeds of milk and cream plus antacids hourly midway between the milk feeds. The gastric contents were aspirated just before each feed—i.e., half an hour after the antacid was given. They found that milk and cream feeds alone (3 oz. total volume, made up of equal parts) had no effect after one hour, although others have found that larger volumes or more frequent feeds were very effective, as described above. A general diet raised the pH somewhat.

A number of antacids in various doses, and atropine, were tested. 2 g. CaCO_3 hourly raised the pH from 1.75 to 4.35, 2 g. magnesium carbonate from pH 1.9 to 5.1, 2 g. magnesium trisilicate from pH 1.95 to 2.57, 2 g. $\text{Ca}_3(\text{PO}_4)_2$ from pH 1.75 to 2.61, 2 g. $\text{Mg}_3(\text{PO}_4)_2$ from pH 1.65 to 3.06, and 30 c.cm. (1 fl. oz.) $\text{Al}(\text{OH})_3$ from pH 1.9 to 3.0. Atropine enhanced the action of CaCO_3 , but had little effect on the other drugs.

The order of efficiency of drugs acting alone in equal (2-g.) doses was: (1) calcium carbonate; (2) magnesium carbonate; (3) tribasic magnesium phosphate; (4) tribasic calcium phosphate; (5) magnesium trisilicate. 30 c.cm. (1 fl. oz.) of 5% colloidal aluminium hydroxide is probably little inferior to calcium and magnesium carbonates.

Breuhaus and Eyerly (1941) studied the effects of antacids in man by recording the intragastric pH at 5-minute intervals for two hours. $\text{Ca}_3(\text{PO}_4)_2$, $\text{Mg}_3(\text{PO}_4)_2$, and CaCO_3 in doses of 1–1.3 g. raised the pH more effectively than 1.3 g. of NaHCO_3 , 10 c.cm. of colloidal $\text{Al}(\text{OH})_3$, or 0.65 g. of $\text{Mg}_2\text{Si}_2\text{O}_7$, and the effects were not necessarily proportional to the neutralizing capacity *in vitro*. This was particularly well shown when mucin was compared with the tribasic powders or CaCO_3 : 10 g. of mucin *in vitro* neutralized as much acid as 1 g. CaCO_3 or $\text{Mg}_3(\text{PO}_4)_2$, but in the stomach mucin was much less efficient than either of the salts. This was probably due to the inadequate distribution of the mucin in the stomach—obviously a question of prime importance. It was also shown that 90 c.cm. of milk half-hourly was inferior only to the tribasic powders and CaCO_3 .

Bennett and Gill (1939) have demonstrated the efficiency of colloidal aluminium hydroxide in patients with peptic ulcer (see Fig. 6). Suggestions have also been made by Schiffrin and

FIG. 6.—Milk plus aluminium hydroxide (Bennett and Gill, 1939).

Komarov (1941) that aluminium hydroxide and phosphate inactivate pepsin even at pH 1–2, but their work has been criticized on technical grounds by Schoch and Fogelson (1942).

It is unlikely that methods of treatment in which two-hourly milk feeds are given, with antacids halfway between, would be as efficient in neutralizing free HCl as the hourly administrations of Kirsner and Palmer; so a pH of 4 will probably not be reached for very long, and at night there will be no neutralization on either regime. Since the majority of peptic ulcers heal readily it may well be that complete inactivation of pepsin is unnecessary and that a pH of 2–3 will cause sufficient reduction of proteolytic activity. We do not know the answer to this question, but if an ulcer does not heal it is important to determine free HCl or pH levels of gastric contents to see how much neutralization has occurred. We have seen cases in which free acid levels increased when antacids were added to a two-hourly milk-feed regime, and such patients would probably require continuous drips of milk or colloidal $\text{Al}(\text{OH})_3$ to control free HCl levels adequately.

Summary

The immediate aim of peptic ulcer therapy is to inactivate the pepsin of gastric juice by raising the pH of gastric contents to 3.5–4. Neutralization to pH 7 is unnecessary, and may easily produce alkalosis.

Milk, magnesium carbonate, calcium carbonate, tribasic magnesium and calcium phosphates, colloidal aluminium hydroxide, and magnesium trisilicate are the most efficient and safe neutralizing agents.

Our own observations were made on patients in the Courtauld Research Ward of the Middlesex Hospital before the war, and we are grateful to Dr. T. Izod Bennett for permission to study his patients. We should like to thank Prof. Samson Wright for his advice and criticism.

A PRECISION METHOD OF CEPHALOMETRY AND PELVIMETRY

BY

PAUL CAVE, M.B., B.S., D.M.R.E.

No method of cephalometry in common use hitherto can claim to be a method of precision. Each is based upon a preliminary estimate (not upon exact measurement) of the height of the "greatest circular section" of the skull above the film. Measurements based upon estimates can never be consistently accurate. The essential features of the various methods are as follows:

Reece (1935) palpates the head, makes allowance for the thickness of the abdominal wall, and adds 2 in. to the tube-skull distance. Thoms (1927) estimates the height and inclination of the occipito-frontal diameter with the patient in the supine position, and after exposure of the film makes another exposure with a perforated lead strip placed above the couch at the height and in the plane of the occipito-frontal diameter. Rowden (1935) measures the foetal skull with the patient in the sitting position, using cephalic scale strips placed at the estimated level of the foetal skull. Walton (1931) and McDonogh (1935) take lateral views of the patient lying either prone or supine with lead marks or a graduated lead rule at right angles to the couch in order to determine the height of the skull above the film. Roberts (1935) examines the patient in the prone position without using a Potter-Bucky diaphragm, and measures the suboccipito-bregmatic diameter on the basis that at term the true diameter of 3½ in. results in a film diameter of 4 in. Chassar Moir (1941) uses a lateral view with the tube at 5-ft. distance and with a scale interposed at the mid-plane of the pelvis. He claims that this gives a fairly accurate guide to the size of the foetal head in about 75% of cases.

It is obvious that in all these methods there is a margin of possible error. For instance, the thickness of the abdominal wall can be estimated but it cannot be measured. The taking of a lateral film in breech cases does not definitely establish the depth of the foetal skull, as the foetus may have moved in the interval between the exposure of the A.-P. and lateral views. A serious disadvantage of these methods is that they require the whole-time supervision of a radiologist. No radiologist should be expected to take the responsibility of calculating the size of a foetal skull from factors not estimated by him personally. These are some of the reasons why

several separate examinations with the patient rotated in oblique positions in order to bring each diameter in turn parallel with the film. Linear objects can be measured provided that they are parallel with the film.

The calculation of the size of the tumour or cavity in the lung and its depth from any part of the chest wall is a simple matter. A double exposure on one film will suffice, or two separate films may be taken if preferred. The method can be used as a check on tomography. The size and depth of opaque cerebral tumours could be determined in a similar manner. The dimensions of a vesical or biliary calculus, or other opaque object, could be determined and compared with its dimensions at a subsequent examination. The results would be comparable even though the position of the object had changed. No doubt other applications of this method will present themselves.

Summary

A new radiometric method is described.

It is claimed to be a method of precision, as the human factor in first estimating the distance of the object from the film is eliminated.

The application of the method to cephalometry and pelvimetry is described in detail.

Other applications in surgery of the brain, chest, abdomen, and pelvis are indicated.

INTRAMUSCULAR INJECTION OF MEPACRINE (ATEBRIN): HISTOLOGICAL EFFECT

BY

FRANK HAWKING, D.M.

(From the National Institute for Medical Research, London)

This note describes a histological examination of the effect of injecting mepacrine methanesulphonate (atebrin musonate) intramuscularly. Owing to the shortage of quinine, mepacrine will be used more extensively than in the past. When oral administration is impracticable it will be necessary to inject the drug intramuscularly or intravenously; in order to assist the choice between these two routes information is presented about the local effects caused by intramuscular injection.

Literature

Many clinical observations on the subject have been reported, but histological observations have not been described. Field, Niven, and Guest (1937) injected two doses each of 0.375 g. musonate into 284 patients. Local reactions were usually unimportant, but occasionally there was a little tenderness and induration at the site; in one case an abscess with atebri-stained contents developed. During the Ceylon malaria epidemic (1934-5) 681 patients were treated with similar doses; 21.3% developed pain at the site of injection, and in two cases abscesses occurred. (When quinine was injected 36% of 424 patients suffered from pain, but there were no abscesses.) In a later series of 530 cases treated in the field most patients complained of pain for 2 to 4 days, some suffered from painful swelling and induration at the site, and in two instances abscesses resulted. Pain after the injection of atebri was less frequent than after the injection of quinine; it might be severe. Abscesses were indolent and slow to heal; they were similar to those caused by quinine, and tracked along the fascial planes in the same way. Hay, Spaar, and Ludovici (1935) treated 3,500 cases; pain was negligible and no abscesses were observed. Simeons (1936) injected two doses each of 0.3 g. into 2,800

people. With good aseptic technique no abscesses occurred; but with a second series of 2,800 cases, in which asepsis was less satisfactory, there were 49 abscesses. Clinical series in which the local reactions were considered as unimportant are also reported by Carman and Cormack (1936), Eckhardt (1933), Kröber (1936), Seelig and Singh (1936), Sicault (1934), Siegenbeek van Henkelom and Overbeek (1938), van Slype (1935), Vardy (1935). Dove (1942) recommends the intramuscular injection of atebri as being less harmful than quinine. The injection is not painful, and if done with sterile precautions will not cause abscesses; Dove prefers it to intravenous injection of atebri.

Experimentally Hecht (1933) injected 0.1 c.cm. of a 1% solution of the hydrochloride—i.e., 1 mg.—apparently subcutaneously; it caused hyperaemic swelling, which disappeared in 24 to 48 hours without necrosis. Hicks (1935) injected 10 to 20 mg. atebri musonate intramuscularly into 8 monkeys, which were killed two days later. In one case he found macroscopically an area of congestion 1×0.5 cm., haemorrhage, and oedema, but the rest showed no gross changes; no histological observations were made.

Summing up the literature, it is generally considered that the intramuscular injection of atebri is as a rule innocuous, but pain and swelling occur in some patients, and, rarely, abscesses may result.

Experimental Results

The present experiments were made by injecting mepacrine methanesulphonate (quinacrine), 50 mg. in 0.5 c.cm. of distilled water, into rabbits weighing 1.5 to 2 kg. Most of the injections were made into the muscles of the thigh or of the loin, but some were made under the skin of the abdominal wall. If larger quantities—e.g., 70 mg. per kg.—were injected the rabbits were often prostrated in about 5 minutes, and some died; apparently absorption is very rapid. Injections were also made into rats. The rabbits were killed after 1 to 5 days and the rats after 1 to 14 days; the site was excised, fixed in formal-saline, and examined by the usual histological methods.

Naked-eye Appearances.—After intramuscular injection the macroscopic evidence of injury was usually slight. The muscles might be somewhat swollen and small haemorrhages might be present along the needle track. In the thigh, the intermuscular space along the sciatic nerve was often stained yellow from hip to knee. But in most cases there was little to be seen, and the site of injection was often difficult to identify. After subcutaneous injection the skin was usually greatly swollen, sometimes becoming as much as 1 cm. in thickness, the swollen area being 4 cm. in diameter. The swelling occurred in the connective tissue of the skin, which was stained yellow and distended with fluid. After 5 days the affected part was converted into a hard dry necrotic mass. The underlying muscles were little affected.

Microscopical Appearances.—Sections taken 1 to 2 days after intramuscular injection showed areas of necrosis in the muscles. The affected fibres were swollen, structureless, and eosinophilic and the nuclei were destroyed. A moderate amount of fluid (often albuminous) was present between the fibres, but cell infiltration was minimal. The areas of necrosis seen on the slide (transverse section) measured 0.5 to 1 cm. across, but the probably extended over a greater distance in the longitudinal direction. In cases in which the site involved an intermuscular space the connective tissue was greatly distended with fluid and a moderate number of cells, most of the cellular elements being necrotic. Nerve trunks showed haemorrhage and degenerative changes, and the outer coats of the larger blood vessels were necrotic. The necrosis also involved the superficial layers of the adjacent muscles. At the edges of the necrotic region there were moderate collections of cells. In the adjacent areas the muscle fibres were often swollen, and stained irregularly. After 4 to 5 days the cellular reaction around the area of necrosis was more pronounced, granulation tissue began to appear, and a zone of demarcation became established.

After subcutaneous injection the appearances were similar. The deeper connective tissue of the skin was greatly swollen with fluid, and towards the edges it was patchily infiltrated with cells, many of which were degenerate; the whole tissue had undergone necrosis over a considerable area. The skin

cutaneous layer of muscle was necrotic; the epithelium was limited in extent, it being apparently more resistant than the deeper tissues.

In rats the histological reaction was similar. When 0.75 mg. dissolved in 0.15 c.cm. was injected intramuscularly the lesion was small, but when it was injected subcutaneously considerable oedema and necrosis occurred. When 20 mg. in 0.3 c.cm. was injected very extensive oedema and necrosis occurred, whichever route was employed.

The damage caused by mepacrine was compared with that caused by quinine. The monohydrochloride was employed. This is less acid than the more soluble bihydrochloride generally used clinically, and consequently the lesions should be less extensive, being due only to the quinine radical and not to the acid part.

When 20 mg. dissolved in 0.6 c.cm. of water was injected intramuscularly into rabbits the lesions were closely similar in appearance and extent to those caused by 50 mg. of mepacrine. In rats the lesions produced by 10 mg. of quinine were less extensive than those produced by 20 mg. of mepacrine, but those caused by 4.5 mg. of quinine were greater than those caused by 0.75 mg. of mepacrine.

Discussion

Since the macroscopic evidence of injury is usually slight compared with the microscopic evidence, the present findings are easily reconcilable with those reported in the literature. They show that the intramuscular injection of mepacrine always causes a limited area of necrosis around the site of injection, presumably due in large part to the direct action of the mepacrine base. With 0.375 g. (as for man) instead of 0.05 g., the extent of the damage would be somewhat larger, but still not great enough to constitute an absolute contra-indication to the practice in selected cases. As compared with quinine, the damage caused by 50 mg. of mepacrine was similar in extent to that caused by only 20 mg. of quinine. Since the standard dose of mepacrine methanesulphonate (by intramuscular injection) is 0.375 g., while an average dose of quinine is 0.5 g. ($7\frac{1}{2}$ gr.) of the bihydrochloride (which is more acid than the monohydrochloride and possibly more injurious locally), it would seem that a therapeutic injection of mepacrine should cause less than a third of the damage done by a therapeutic injection of quinine.

The relative and absolute merits and demerits of the administration of mepacrine by intramuscular injection cannot properly be discussed here. According to Hecht (1936) most of the mepacrine is absorbed from the site in one to three hours; and this statement about the rapid absorption is in agreement with my own experience and with the reports reviewed above. Clearly, mepacrine should not be injected by any route unless it is impracticable to give it by mouth. The intravenous route avoids local damage, but entails a certain risk to life unless the injection is given very slowly; the intramuscular route is certain to cause a small amount of local injury, but the risk to life from over-rapid absorption is much less (although this is not absolutely excluded, since 4 patients died from mepacrine intoxication out of the 681 treated by intramuscular injection during the Ceylon epidemic). The choice between the two routes of injection must depend upon clinical experience and upon the discretion of the medical man responsible for the case.

Summary

A review of the literature shows that intramuscular injection of mepacrine (atebrin) is considered to be free from local reaction in most cases, to cause pain and swelling in some cases, and to cause local abscesses in rare cases.

Mepacrine methanesulphonate (atebrin musonate) was injected intramuscularly and subcutaneously into rabbits and rats. The macroscopic lesions were often inconspicuous, but microscopic examination always showed a certain amount of necrosis at the site of injection. The damage caused by a therapeutic injection of mepacrine is similar in kind to that caused by a therapeutic injection of quinine, but probably less than one-third as extensive. For patients who cannot take mepacrine by mouth this local damage does not contraindicate parenteral injection, but its occurrence should be borne in mind when choosing between the intramuscular and the intravenous routes.

Grateful acknowledgments are due to Sir S. Rickard Christophers for his encouragement and advice, to Messrs. May and Baker Ltd.

for the supply of the compound, to Mr. F. J. Higginson for the histological preparations, and to Miss R. J. Berson for technical assistance.

POST-VACCINAL ENCEPHALOMYELITIS

BY

SAMUEL DUNN, M.D.

The nervous complications of vaccination have been recognized for many years. Turnbull (Turnbull and McIntosh, 1926) reported a fatal case occurring in 1912, but chief interest in the condition arose after 1923. The Report of the Committee on Vaccination was issued in 1928. The cause of the nervous complications of vaccination is still unknown. The condition very rarely follows vaccination in infancy; adults who are undergoing their primary vaccination are most susceptible. The patient whose case is described below had been successfully vaccinated in infancy: a well-marked scar could be seen close to the present pustule. According to her, considerable bleeding occurred at the time of the vaccination, and it seems likely that a "cross-hatching" method was employed. Some authorities consider that linear scratches are not so likely to be followed by nervous complications as "cross-hatching" methods.

In this patient the cerebral symptoms preceded the spinal symptoms by two days, and consisted of lethargy, mental confusion, and insomnia. The interval between vaccination and the onset of symptoms was 15 days; the average period is said to be about 12 days. The paraplegia developed very rapidly, and was complete in 12 hours. Bronchopneumonia and cystitis are the usual causes of death. In the present case cystitis gave rise to the main anxiety. Sulphanilamide certainly kept the urinary infection within bounds, but had no apparent effect on the nervous symptoms. On the whole the administration of plasma appeared to be beneficial, but it is difficult to estimate its value in a condition such as this, in which there is a strong tendency to spontaneous recovery. The plasma seemed to have a very favourable influence on the mental symptoms; these passed off after the first dose. The mortality of post-vaccinal encephalomyelitis is between 50 and 60%, but the prognosis is probably better in the spinal forms than in the severe cerebral types.

As a result of experience in treating the present case it is advised that suitable serum or plasma should be given as soon as possible. This is obtained from a person vaccinated about 21 days earlier. When mass vaccination is going on at the time there will probably be little difficulty in obtaining a suitable donor. In other circumstances it would be necessary to vaccinate a donor; the interval of waiting before the plasma can be obtained would then be a great drawback. One might seek some service or institution—e.g., a hospital—where the entrants must be vaccinated before admission, and it might be possible to find there a recently vaccinated individual who would consent to act as donor. The plasma used in the present case contained 3.8% sodium citrate solution. Originally 50 c.cm. of citrate was added to the blood as preservative; 220 c.cm. of plasma was obtained, and presumably nearly all the citrate was in the plasma.

It is interesting to note that the patient had an attack of tetany during the administration of the plasma. There had

been some vomiting before the attack. Her chief complaint was of agonizing pains in the arms, for which large doses of morphine were given.

REPORT OF CASE

The patient was a woman aged 21, a school teacher. Vaccination had been successfully performed in infancy. She was in good health when vaccinated on July 9, 1942, and a few days later travelled to Glasgow. She was first seen on July 20, when she complained of a very painful arm which kept her awake at night. There was a well-marked reaction around the pustule, with a little oedema of the arm, but no signs of sepsis were present, and the glands in the axilla and the neck were not enlarged.

On July 24 she complained of feeling easily tired; she became drowsy and took little food; on the following day she could be aroused only with difficulty, and considerable mental confusion was present. On the 26th she was very drowsy; the temperature and pulse rate were normal. The vaccination area was covered by a thick scab. She had passed no urine for 24 hours. Examination showed a flaccid paraplegia. There was complete loss of sensation over the lower limbs and over the abdominal wall below the level of the umbilicus. The abdominal muscles were flaccid and there was considerable abdominal distension, even after emptying the bladder by catheter. The knee-jerks were present at this stage but disappeared a few days later. The plantar reflexes could not be elicited. The fundi and external ocular muscles showed no abnormality. The pupils were dilated and reacted sluggishly to light. Mental confusion was pronounced. On the 27th she complained of pain in the neck. The posterior neck muscles were tender to the touch, but there was no nuchal rigidity and Kernig's sign was absent. She required regular catheterization. Constipation was marked, and repeated enemata gave no result. The temperature rose to 100° F.

On July 28 the patient could move the toes of the left foot. She began to have severe pains in the arms and had to have morphine regularly. These pains persisted for about three weeks. The urine was now heavily infected and the temperature was continuously raised. She was restless and delirious and had frequent attacks of vomiting. Sulphanilamide was given, a total of 18 g. being administered in a week. On Aug. 5, when her condition was giving rise to the most acute anxiety, she passed some urine into the bed. This incontinence persisted for another 10 days, but the urinary infection soon passed off. At this date she had no sensation in the lower limbs and the mental confusion was still present. On Aug. 6 she had slight rotatory movements at each hip-joint. During the day she was somnolent and at night restless and excited. On Aug. 20 plasma was obtained from a recently vaccinated individual, and 20 c.cm. was administered intramuscularly each day. The patient's mental condition improved after the first injection, and in two days was normal. The abdominal muscles regained their tone, and after a period of persistent vomiting the distension passed off. On Aug. 25, after 100 c.cm. of plasma had been given, she had an attack of tetany. Plasma administration was stopped for two days and then restarted, using smaller doses. A further 120 c.cm. was given. Several attacks of tetany of less duration occurred.

From this date the patient rapidly recovered the movements of the limbs—first dorsiflexion of the ankles, then flexion of the hip-joints, and then flexion of the knee-joints. On Sept. 4 the left plantar reflex was extensor. Sensation was not yet fully restored. Deep sensibility seemed to be normal, but she had difficulty in locating touch and pain and in distinguishing between the finer grades of temperature. There was slight atrophy of the muscles of the thighs. On Sept. 9 the left knee-jerk was elicited for the first time since it was lost at the beginning of the illness. She still had imperfect bladder control. By the 13th she could raise each leg from the bed, and by the 23rd could shuffle a few steps.

Thereafter she progressed rapidly. On Dec. 24 the only muscular weakness which could be made out was in the extension of the right big toe and in dorsiflexion of the right ankle. She had difficulty in distinguishing between the finer grades of temperature, and her tactile localization was still deficient over the lower limbs. Her bladder control was normal, but she still had a little frequency. She began work early in Jan., 1943.

I wish to thank Dr. George Allan and Prof. T. K. Monro of Glasgow for their advice when they saw the case in consultation with me; to the latter I am also grateful for making arrangements to obtain the special plasma from the Glasgow and West of Scotland Blood Transfusion Service.

According to A. J. Mueller and others (*Johns Hopk. Hosp. Bull.*, 72, 110) the minimum requirements of enzymic casein hydrolysate for maintenance is between 0.4 and 0.7 g. per kilo. This indicates its approximate equivalence with intact protein for maintenance, since maintenance of the latter is usually regarded as between 0.4 and 0.7 g. per kilo.

Medical Memoranda

Kienböck's Disease: Aetiology

Kienböck's disease of the semilunar bone is by no means rare and is described in most textbooks. It is regarded by many authors as being of the same class as Köhler's disease of the tarsal scaphoid, Calvé's disease of the spine, and Perthes' disease of the head of the femur. But whereas these, being essential epiphyseal in origin, are found in children, Kienböck's disease is found only in adults. The typical case shows a syndrome consisting of pain over the semilunar bone, limited movement of the wrist, possible ultimate retraction of the head of the third metacarpal, and degeneration of the semilunar seen in radiographs. Most authors agree that the condition is fundamentally an avascular necrosis (Maingot, 1939; Handfield-Jones and Porritt, 1940), but there is a divergence of opinion concerning the aetiology. It is for this reason that the following cases are published.

CASE HISTORIES

Case 1.—A leading aircraftman aged 33 reported sick on April 1, 1942, complaining of pain in the right wrist. Three years previously he had had a septic left thumb, which healed on treatment. Shortly afterwards, for no apparent reason, the right wrist became painful. He was treated for neuritis of the wrist for three years without improvement. No radiograph was taken. He denied having ever sprained or sustained any injury to the wrist. On examination the right wrist showed no obvious deformity. Palmar flexion was limited; extension was normal. Passive adduction caused pain on the radial side of the joint. Tenderness was elicited over the semilunar bone on the dorsal surface, and over the scaphoid in the "anatomic snuffbox." There was no shortening of the metacarpal head. Radiographs showed gross disorganization of the semilunar bone with irregular absorption of bony trabeculation. The degree of opacity indicated avascular necrosis of the bone. Arthritic changes were seen around the cuneiform and the articular surfaces of the radius. Diagnosis: Kienböck's disease.

Case 2.—A gunner aged 30 was seen on May 9, 1942. He complained of pain in the left wrist of one year's duration, and had been treated for a sprained wrist for that period of time without improvement. No radiograph was taken. Injury or trauma was emphatically denied. No septic focus could be remembered, but dental treatment had been necessary some time previously. On examination the wrist showed no obvious deformity or swelling. Palmar flexion was limited; extension was normal. Passive adduction caused pain on the radial side of the joint, and tenderness was elicited by pressure on the radial and ulnar sides: the pain was transmitted to the semilunar area. Pressure over the semilunar bone itself caused sharp pain. There was no retraction of the head of the third metacarpal. Radiographs showed gross disorganization of the semilunar bone with arthritic changes around the articular surfaces of the radius and the scaphoid. The degree of opacity indicated avascular necrosis. Diagnosis: Kienböck's disease.

COMMENTS

It is stated (McGregor, 1939) that the nutrient artery to the semilunar bone is carried by the posterior ligament, which consists of the deep fibres of the dorsal radio-carpal ligament. The commonest fracture of the bone is a separation of a small fragment from the posterior part (Hosford, 1939). If this fracture involves the nutrient foramina and interferes with the blood supply, then avascular necrosis will follow. Watson Jones (1941) states that there is also an anterior nutrient artery which enters via the anterior ligament, and it is only when both supplies are completely cut off, as in complete dislocation of the bone with rupture of the ligaments, that avascular necrosis occurs. Rupture of the posterior ligament alone is not usually sufficient to interfere with adequate nutrition.

Many authors assert that trauma involving the blood supply is the aetiological factor in producing Kienböck's disease; others say the cause is unknown. In Case 1 there is no history of trauma, but of a septic focus. It seems, therefore, that in this instance the condition is the result of the entry of organism of mild virulence, and a sequel of an osteitis.

Case 2 also gives no history of trauma, but the possibility of a septic focus (teeth) cannot be dismissed. It appears that when trauma can be definitely excluded haematogenous infection must be considered as an aetiological factor in producing the condition known as Kienböck's disease.

SUMMARY AND CONCLUSIONS

Two cases of Kienböck's disease are described. The possibility of bacterial infection as an aetiological factor is suggested in cases not directly attributable to injury. The need for x-ray examination in all cases of injury and disability of the wrist-joint is indicated, with follow-up radiography later in all cases that do not respond to treatment.

Urea for Migraine

A man aged 42, employed as a clerk, had suffered for several years from severe headaches with acute exacerbations of migraine type. Many drugs had been tried without success, and he was admitted to hospital under Dr. A. P. Thomson for investigation with a view to operation for cerebral decompression. There were no abnormal signs on physical examination. X-ray films of the skull, cerebrospinal fluid before and during an attack, urea-concentration test—all were normal. The blood urea during an attack was 88 mg. per 100 c.cm. After taking 5 g. of urea for a urea-concentration test the patient was next morning free from headache for the first time for several weeks. On the chance that this might be *propter* and not just *post*, it was decided to continue the urea in 20-gr. doses daily. Headaches did not return; no attack of migraine developed. The patient was discharged from hospital with a recommendation to go on taking urea. This course was adopted, and there has been no recurrence of migraine or severe headache for the past 9 years, except during periods when the patient has given up the regular use of urea. One hesitates to add to the long list of remedies for migraine, but during the last 8½ years I have used urea with such success both for typical migraine and for persistent headache not typically migrainous that I wish to bring the treatment to the notice of others, fully aware that my evidence is incomplete.

The headache usually disappears after a short course of treatment, and in cases of typical migraine the attacks do not recur or are so modified as to make them bearable so long as the patient continues treatment, which is as follows: 20 gr. of urea in water three times a day for a week; a similar dose twice a day for a week; subsequently 20 gr. in a single daily dose for an indefinite period. There are no untoward effects.

Here are thumbnail notes of 3 cases: (1) A male aged 55 had frequent attacks of migraine with hemianopia. Treatment with urea brings great relief, but he relapses to typical attacks if he neglects taking his daily dose. (2) A male aged 57, from the age of 7 suffered periodically from attacks of headache which lasted as a rule for several days, occasionally developing into typical migraine. Since taking urea he has had no severe attack of headache for 8 years. (3) A female aged 35 had monthly attacks. She has had no attacks during the last 18 months (while taking urea), and now leads a normal life.

Goldzieher¹ in a paper on the "Endocrine Aspects of Headache" reports 50 consecutive cases of severe headaches, most of which were of the characteristic migraine type. Oliguria was a distinct feature in most, the twenty-four-hour specimens showing an average sodium chloride content of only 6.7 g. A salt-tolerance test indicated a retention of 73% of the test salt for the whole group, accompanied by water retention. Goldzieher postulates a breakdown in the metabolism of salt and water, and explains migraine headaches as the result of increased intracranial pressure. He says: "They develop when increased permeability of the capillaries permits increased flow of water to, and subsequent retention in, tissues which have stored abnormal quantities of sodium salts."

The diuretic effect of urea is well known, and it may be that it is this which corrects the temporarily disturbed balance that results in an attack of migraine.

Birmingham.

¹ *J. Lab. clin. Med.*, 1941, 27, 150.

H. Gold (*Arch. intern. Med.*, 1942, 70, 785) records his observations on 60 cases of anthrax which he has seen since March, 1933; 41 were males and 19 females. The ages ranged from 3½ to 62 years, but most were between 18 and 27. Anti-anthrax serum was given intravenously to 21 patients, with only 1 death; neoarsphenamine given in addition to the serum was of little or no benefit. In 42 cases treatment consisted in administration of sulphamide compounds, with excellent results in 30 cases. Sulphapyridine was the most effective compound; next came sulphathiazole and then sulphadiazine.

Reviews

SEARCHLIGHT ON THE CAPE

Official Report of the Social Survey Conference, Cape Town, 1942.
(5s. 6d.) Capetown: Paul Koston, 1943.

A social survey conference was held in Capetown last year, following upon a survey which had revealed some disquieting things about the health and economic standards of the coloured population. The papers and discussions—some of them in Afrikaans, but summaries in English are given—cover a wide range. Some remarkable facts are set out by Prof. T. S. Higgins, medical officer of health for Capetown. It is shown that, while the infant death rate for Europeans in the municipality is below that for England and Wales, the rate for non-Europeans is three times as high. Another significant fact is the prevalence of tuberculosis. In the last year for which there were figures the death rate from tuberculosis among non-Europeans was 425 per 100,000 of the population—this in a city where the average annual sunshine record is 7½ hours a day, compared with something like 3½ hours in London. Dr. J. H. Harvey Pirie, president of the Federal Council, Medical Association of South Africa (B.M.A.), urges the establishment of a joint Ministry of Health and Social Welfare to take over the present incoordinated services, but to avoid the capture of such an organization by the political machine he would have the technical control of the services delegated to a health commission, and not run directly by a State Department. There was a curious repetition at this conference of the ideas and controversies at present stirring medical politics in this country. The conference carried resolutions about hospital beds and health education and a comprehensive medical service, and then it went on to urge the Government to investigate methods of removing tariffs and prohibitions on the importation of health-giving foodstuffs and all systems of internal control which involve raising of food prices. The document is not easy to read, but the student of sociology will find it interesting.

DEGENERATIVE JOINT DISEASE

Changes in the Knee Joint at Various Ages: With Particular Reference to the Nature and Development of Degenerative Joint Disease. By G. A. Bennett, M.D., H. Waine, M.D., and Walter Bauer, M.D. (Pp. 97; illustrated. 52.50 or 14s.) New York: The Commonwealth Fund; London: Oxford University Press, 1942.

The authors of this work have devoted many years to the study of chronic rheumatic disorders, and here record the results of an investigation into the changes in the knee-joints in a large number of individuals who had no history of articular disease. They have thus established what they term a "norm" for the knee-joint at each age decade, and have shown that degenerative changes begin to make their appearance very soon after normal development has been completed. After the second decade superficial fraying of the weight-bearing surfaces begins to appear and progresses to roughening and splitting of the articular cartilage; extensive damage was found before any changes in the x-ray appearances could be detected. Lipping of the bones was not met with till the fifth decade, except in one case. The observations supported the findings of other investigators that the initial anatomically demonstrable lesion is a degenerative process in the superficial layer of articular cartilage, the criteria for an infectious lesion were never present, while evidence of inflammation appeared only in the most advanced cases. A remarkable feature is that Bennett, Waine, and Bauer found no convincing evidence that degenerative joint disease is more common in individuals who have done strenuous labour than in those who have led sedentary lives, and they also agree with Llewellyn and many others that any direct evidence of causal relationship with arteriosclerosis is entirely lacking; one case which in the seventh decade showed the least deviation from the normal of all those examined at this age had arteriosclerosis and gangrene of the foot. They arrive at the conclusion that degenerative joint disease appears to be related to the senescence of joint tissues, varying to a certain degree with the hereditary endowment of the individual, but that what brings about the ageing of articular structures is an unsolved problem.

This is a most valuable piece of research, studying changes as they develop from the normal to the pathological, and furnishes a starting-point for further work which should be of great value in the elucidation of the problems of chronic rheumatic disease.

REGIONAL ANATOMY

A Synopsis of Regional Anatomy. By T. B. Johnston, M.D. Fifth edition. (Pp. 424; illustrated, 16s.) London: J. and A. Churchill, 1943.

A fifth edition of Prof. T. B. Johnston's synopsis has now been reached, and it fully sustains the character of his previous work. The book is designed to meet the needs of students who have already gained a preliminary knowledge of anatomy in the course of their practical work in the dissecting-room, but who after clinical experience, acquired during the later stages of their training, wish to revise their earlier anatomical work in the light of its application to medical and surgical practice. It is evident from the author's foreword that he does not seek to substitute a *synopsis* of regional anatomy for the more complete descriptions of the larger textbooks on systematic anatomy, but rather to supplement revision of these by a short survey of the more important facts of regional anatomy studied from the applied point of view. As one might expect from Prof. Johnston special attention has been devoted to the description of the central and peripheral nervous systems, and the bearing that an accurate knowledge of the peripheral distribution of the various types of sensory and motor nerves, and of the correlated tracts in the central nervous system, has upon diagnosis and treatment. This section has been brought up to date and includes topographical data concerning recent work on the thalamic and hypothalamic nuclei and tracts. These sections, and these sections only, are illustrated, the figures being diagrammatic and simple. The diagrams are for the most part adequate and serve their purpose. Fig. 17, however, shows an unnecessary and considerable dislocation with regard to the position of the hypothalamic nuclei and corpora albicantia, and the mode of spelling the adjective "somesthetic" is likely to offend the sensibility of classical scholars. The general excellence of the book, however, should not be judged from the above examples, and it may confidently be recommended to senior students as a valuable summary of the more essential points of regional anatomy.

Notes on Books

In the third edition of Dr. W. V. THORPE'S *Biochemistry for Medical Students* (J. and A. Churchill; 16s.) the author has correctly appreciated the true nature of his charge, which is a discussion of the chemical reactions induced by biological agency within the living organism, for the study of this relates to the functions of life and reaches beyond the chemistry of the matters composing the organism itself. It is a book which fully meets the requirements of medical students, omitting nothing of fundamental importance even among the quickly advancing discoveries in this branch of science; it is well suited for the student's purpose, and its value is further enhanced by the author's gift for producing easy reading. It is not only a book for students; it is no less valuable as a book of reference.

Dr. CHARLES WORTHAM BROOK, having read a biography of Richard Carlile (1790-1843), came across a reference to Sir William Lawrence, and this started him upon a hunt for traces of progressive leaders of the medical profession who may have been known to Carlile—a man described by G. J. Holyoake as "having done more than any other Englishman in his day for the freedom of the Press." Carlile was kept in Dorchester Gaol for six years for publishing political works frowned on by authority, and suffered in all nearly ten years' imprisonment for his vindication of a free Press. Under the title *Carlile and the Surgeons* Dr. Brook has compiled a pamphlet (Strickland Press, 104, George Street, Glasgow; 2s. 3d.). This includes an open letter to the Mayor of Dorchester, who was also surgeon to the gaol, in which Carlile vigorously supported the medical reform movement; some historical matter about William Lawrence's "desertion and betrayal of Wakley and the medical reformers in 1828," and about Joseph Hume, described as "the surgeon who became a party leader"; also an extract from the *Lancet* of Feb. 18, 1843, in which Thomas Wakley commended the bequest by Carlile of his body for dissection at St. Thomas's Hospital.

Volume LXII of the *Transactions of the Ophthalmological Society of the United Kingdom*, for the year 1942, is published by J. and A. Churchill at £2. The chief discussions reported are those on the value of sulphonamides in ophthalmology, opened by Major G. Scott and Mr. Arnold Sorsby, and on the role of vitamins in ophthalmology, opened by Dr. Raymond Greene and Mr. F. Williamson-Noble. These are followed by papers on trachomatous tumour of the conjunctiva simulating tubercle, on "white ring" in the cornea, on malignant melanoma of the iris, on retinal disease on glaucoma, and on diseases of the optic nerve. The miscellaneous papers include one on anaesthetics for ophthalmic operations, another on the extraction of magnetic foreign bodies from the vitreous chamber. The Oxford Ophthalmological Congress of 1942 is fully reported, and the volume closes with transactions of the North of England and the Irish Ophthalmological Societies.

The ninth volume (for 1943) in the series entitled *Modern Treatment Year Book* is edited by Surgeon Rear-Admiral C. P. WAKELEY and published at 12s. 6d. by the Medical Press & Co. Ltd. It comprises 26 short articles on a variety of subjects in medicine, surgery, and gynaecology, followed by a group of papers on some injuries and diseases associated with war or on dietetics in wartime. Each contributor writes from personal experience, and the list of authors includes the names of well-known teachers in London and the Provinces. The keynote of the series is brevity; treatment is the main theme.

Officers of the recently formed Indian Army Medical Corps will find much useful information in *A Handbook for Emergency Commissioned Officers of the Indian Medical Service*, by Lieut.-Col. J. R. DOGRA (Bombay: Thacker & Co., Ltd.). The book covers among other subjects, the duties of a regimental medical officer, the organization of the Army in India, the collection and evacuation of casualties, and medical arrangements on active service. A bibliography of relevant official publications is appended to each chapter. There are also nine appendices, one of which comprises a list of sixty-six Army forms, "with which the young medical officer must be completely familiar, and which he should be capable of filling up without the assistance of a clerk or subordinate." An index would have enhanced the value of the book.

Preparations and Appliances

A MOUTH GAG FOR EDENTULOUS PATIENTS

Major H. L. THORNTON, specialist anaesthetist, R.A.M.C., writes:

The device illustrated here was designed to help in the administration of gaseous anaesthetics to edentulous patients. With such patients the difficulty in adapting the facemask accurately enough to exclude all leakage presents a considerable problem, particularly important when a closed-circuit technique has to be employed. I have found, after fairly extensive trial, that this gag overcomes the difficulty in a very satisfactory manner.

The gag is made of partially vulcanized rubber and consists essentially of two curved plates moulded to form a superior and inferior sulcus to accommodate the upper and lower alveolar margins. The plates are separated by lateral pillars, made slightly convex at their outer margins, to provide support for the insides of the cheeks and preserve the normal contours of the face. Centrally there is a wide aperture through which an artificial airway may be admitted, if desired.

The gag may be introduced under very light anaesthesia, or, in the case of patients accustomed to the wearing of dentures, it appears to cause little discomfort if inserted before induction of anaesthesia. I am still using my original model, and after some 5 years of trial have never found an edentulous mouth to which it could not be adapted, whatever the difference in shape and size. The malleability of the rubber and width of the alveolar sulci allow of considerable variation of fitting. The rubber is readily sterilizable by boiling.

The gag is manufactured by Medical and Industrial Equipment Ltd., 12, New Cavendish Street, W.1. I would like to express my indebtedness to Mr. Douglas Hallon, M.R.C.S., L.D.S., for the help he gave me in constructing the experimental models.

ANTIRETICULAR CYTOTOXIC SERUM*

BY

ALEXANDER BOGOMOLETZ

Member of the Academy of Sciences of the U.S.S.R.

physiological system of connective tissue performs within organism very important plastic, trophic, and defensive functions. The struggle of the organism against infectious diseases, and its resistance against the development of tumours, healing of wounds and ulcers, and the union of fractures, depend on the reactivity of the physiological function of the connective tissue.

I have introduced antireticular cytotoxic serum with a view to controlling this reactivity and to stimulating the physiological function of the connective tissue. This serum is obtained by repeated injections of cellular elements of human spleen and bone marrow into horses. Subcutaneous injection of a fairly large dose of antireticular cytotoxic serum (0.05 to 0.1 c.c.m.) exerts a very strong specific stimulating action upon the physiological system of the connective tissue.

In the summer of 1942 a conference was held in Ufa on the therapeutic application of the serum. The conference was attended by professors of the Moscow, Kiev, Kharkov, and Shkirian Medical Institutes as well as by physicians of numerous evacuated hospitals of various districts and cities. More than thirty reports were made.

It has previously been shown by Dr. Oleg Bogomoletz that antireticular cytotoxic serum accelerated the union of fractures. Drs. Ischenki and Lurie have pointed out the efficacy of the serum in treating septic diseases. The Academician Strajeski and in his clinic that acute rheumatism can also be cured by means of this serum, and Prof. Mankovsky has mentioned the favourable effect of antireticular cytotoxic serum on the course of infectious diseases of the nervous system.

Findings of Russian Conference

It was stated by the conference, on the basis of more than 500 clinical cases, that:

"The antireticular cytotoxic serum proposed by the Academician Alexander Bogomoletz is a powerful specific factor affecting the physiological system of the connective tissue, and exerting, when applied in proper small doses, a strong stimulating action upon the cellular elements of that system, as evidenced by a number of experimental studies and clinical observations. The therapeutic application of the above serum is indicated principally in all those cases of diseases which involve a decrease or depression of the functions of the physiological system of the connective tissue.

About 2,500 clinical observations discussed at the conference conclusively show that antireticular cytotoxic serum is therapeutically effective in war traumata and in the following diseases:

1. (a) Particularly slow-uniting bone fractures; (b) slow-healing, slowly granulating, and infected wounds; (c) general suppurative infection, especially in its initial stages; (d) suppurative inflammation of the cavities and tissues; (e) frost-bite and burns of the second and third degrees; (f) infected traumata of the eyes.

2. A number of infectious diseases: (a) cerebrospinal meningitis; (b) puerperal and gynaecological sepsis; (c) rheumatism; (d) unresolved pneumonia and lung abscess; (e) tonsillitis.

3. (a) Traumatic and infectious diseases of the central and peripheral nervous system (neuritis, meningo-encephalitis, diffuse sclerosis); and (b) a number of psychoses, such as schizophrenia and post-infectious, senile, and pre-senile psychoses.

4. Some diseases associated with a disturbance of the trophic function of the tissues: (a) ulcer of the stomach and duodenum; (b) eczema.

In view of the clear-cut therapeutic effect recorded in the above cases a vast-scale introduction of antireticular cytotoxic serum to medical practice of hospitals and civil medical institutions is deemed obligatory."

Clinical Evidence

The clinical evidence presented to the conference is of great interest. Reports have been received of many cases of slow-healing, invalidating gunshot fractures which have healed up within four or five weeks under the influence of the serum, so that the patients could return to the Army. No less numerous are cases in which the serum has increased the

resistance of the organism, thereby favouring prompt recovery from various wound infections.

Prof. Linberg cites a case of gunshot wound of the thigh treated by Dr. V.: "The non-reactive course of the disease lasted about three months. After administration of the serum the course of the disease changed abruptly: there has formed at the site of the fracture a bone callosity." The case of Dr. Koulbaeva: "Patient Z.; gunshot arm-fracture. Absolutely no consolidation; after the first injection of the serum, complete consolidation." Prof. Alymova says: "No callus formation had been noticed in a young soldier four months after fracture of the thigh. Five days after injection of the serum excellent union occurred." Prof. Gorodinsky stated that a comminuted fracture of the thigh which did not heal during nine months united under the influence of the serum. The patient made a complete recovery. Prof. Mikhailovsky reported on the therapeutic effect of the serum in 24 cases of fetid coryza, which was commonly regarded as incurable.

Of great interest is the fact that under the influence of the serum cerebrospinal meningitis in adults assumes a very mild course similar to that occurring in children.

The antireticular cytotoxic serum proposed by me differs essentially from all other kinds of serum. Although its application is indicated in very different diseases it exerts only one kind of action—viz., in small doses it stimulates and in large doses inhibits the functions of the physiological system of the connective tissue. Since, as previously indicated, the physiological system of the connective tissue performs within the organism very important trophic, plastic, and defensive functions, its curative effect becomes quite comprehensible.

I was very well satisfied with the results of the conference, since they show that the above essentially new method of pathogenic therapy may prove of great use. It will accelerate the recovery of many soldiers of the Red Army.

QUEEN'S INSTITUTE REPORT ON MIDWIFERY CASES

A report by the Queen's Institute of District Nursing on midwifery cases attended by Queen's Nurses and village nurse-midwives during the year 1942 shows very satisfactory results, particularly in view of the difficult conditions under which the midwives have worked. In spite of the tendency to enter hospital the number of cases has increased though fewer midwives have been available. The number of cases attended (no doctor engaged for the confinement) was 89,182 (increase of 1,276). The total number of midwives was 4,230, of whom 1,534 were Queen's Nurses and 2,696 were village and other nurse-midwives. Of the patients attended, 23,667 were primiparae. The number of maternal deaths was 104, a maternal mortality rate of 1.17 per thousand.

Analysis of Maternal Death Rates

Per 1,000 Live Births					
Year	Puerperal Sepsis	Other Puerperal Causes	Total Puerperal Mortality	Non-puerperal Causes	Total Maternal Mortality
1940 ..	0.37	1.29	1.66	0.08	1.74
1941 ..	0.22	1.28	1.51	0.07	1.58
1942 ..	0.21	0.89	1.10	0.09	1.19

Per 1,000 Total Births					
Year	Puerperal Sepsis	Other Puerperal Causes	Total Puerperal Mortality	Non-puerperal Causes	Total Maternal Mortality
1940 ..	0.36	1.26	1.62	0.08	1.70
1941 ..	0.23	1.25	1.48	0.07	1.55
1942 ..	0.20	0.87	1.08	0.09	1.17

The number of times medical aid was sent for in 1942 was: for mother, 30,714 (34.4%); that is, during pregnancy 6,090 (6.8%); during labour 21,313 (23.9%); and during puerperium 3,311 (3.7%); for infant, 5,516 (6.2%). The number of forceps cases was 4,495 (5%).

The causes of the 104 maternal deaths in 1942 were: sepsis (18 cases), accidents of labour (36), eclampsia (15), embolism (10), complications (17), non-puerperal (8). There were post-mortem examinations in 27.1% of the maternal deaths, as compared with 22% and 22.8% in the two previous years.

Maternity Nursing.—The number of cases attended (doctor engaged, midwife acting as maternity nurse) was 41,923. Among these the number of maternal deaths was 71 (1.69 per thousand); seven deaths (9.9%) were due to miscarriage. These being doctors' cases the details were not verified.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY AUGUST 14 1943

SULPHONAMIDE TREATMENT

"The Medical Use of Sulphonamides" is the title of M.R.C. War Memorandum No. 10,¹ published on July 30—a pamphlet containing in 46 pages as much practical information as the average full-scale book on its subject, with the added advantage of being completely up to date. The title may mislead: the word "medical" is not used in contradistinction to "surgical," but includes all forms of therapeutic use. This memorandum was prepared by a number of authors on behalf of the Therapeutic Requirements Committee and is defined as a "summary review of the clinical indications for some of the principal sulphonamide drugs, in the light of their present or potential availability in Great Britain, for the assistance of Service and other Departments and for the guidance of medical and hospital officers." The concern of this committee may be seen in this reference to the supply position, but in trying to ensure that those compounds which are in short supply shall be used to the best advantage the members have at the same time produced a general guide to intelligent sulphonamide therapeutics from which almost any clinician has something to gain. It begins with a chemical description of nine principal drugs, and lists some of their trade names, the use of which is emphatically condemned. A section on pharmacology follows, dealing with absorption, distribution, and excretion: this includes a valuable table of the solubilities in water, serum, and urine of eight compounds and seven acetyl derivatives, and information about acetylation, partition between red cells and plasma, and the concentrations usually attainable in the blood from given dosage. It deals also with one principle of fundamental importance—the essentially identical nature of the action of all sulphonamide compounds. It is wrong to suppose that, because one is indicated for this infection and another for that, there is any qualitative difference in action. More resistant bacteria demand treatment by the most active compounds, but otherwise the advantages of each compound depend on other factors, such as the ready solubility of sulphanilamide, the slow excretion of sulphadiazine leading to high blood concentration, and the poor absorption of sulphaguanidine—and still more of succinyl sulphathiazole—which enable them to reach the lower bowel. That all act in essentially the same way might be deduced, if no other proof existed, from the fact that acquired bacterial resistance to one compound is accompanied by an equivalent change in resistance to others.

Dosage is dealt with as a general question, and a full table is given of the amounts indicated as an initial dose and in the three succeeding periods (2 to 3 days, 2 days, 2 days) for four age groups and for both severe and moderate infections. The initial "loading" dose is emphasized, the necessity for continuing administration at night as well as by day, and the inadvisability of continuing treatment for more than 7 days in most cases: indeed, if improvement is not seen much earlier than this, careful inquiry should be made into the reason for it. This includes an estimation of the sulphonamide sensitivity of the infecting organism. It may be remarked that fully controlled treatment calls for laboratory services which are

unavailable to most practitioners and would place a severe strain on the pathological staffs of many hospitals. The number of leucocyte counts which may have to be done if they are seriously looked upon as an essential safeguard against producing agranulocytosis is very large indeed, and if the progress of treatment must regularly or often be followed by estimations of the drug in the blood this alone means a very serious bulk of laboratory work in any large hospital. The estimation of the sulphonamide sensitivity of a particular micro-organism will much less often be necessary, but is a rather more troublesome and generally unfamiliar procedure. These are therefore by way of being counsels of perfection at a time when pathological man-power is so depleted. But this is not to say that every endeavour should not be made to secure such aids to treatment when they are feasible. It is well known that irregular absorption, vomiting, and varying degrees of acetylation may affect the blood concentration attained, and an estimation of this should be the first step in the further investigation of a case not responding to treatment.

The treatment of individual conditions is discussed under 13 main headings, with much shorter sections on 16 others. Other necessary treatment is briefly mentioned when sulphonamides are not to be relied on alone. The order of preference among various compounds is given for each condition, and this involves so many choices on only scanty statistical data that they are presumably not claimed to be infallible. Sulphathiazole is given as the first choice both for cerebrospinal fever and for other forms of purulent meningitis, although it is mentioned that the concentration of this compound attained in the cerebrospinal fluid is only 15 to 40% of that in the blood, whereas the corresponding figures for sulphapyridine and sulphadiazine are 50 to 70% and for sulphanilamide 90 to 100%. It is commonly believed that sulphathiazole is contraindicated in meningitis for this reason, and if in the authors' opinion its greater activity counterbalances this drawback it would have been helpful to say so in so many words. Pneumonia and urinary tract infections are subdivided according to their bacteriology: here, of course, is a province of treatment in which laboratory aid is essential, and it should be much more widely known that, though quite small doses of most sulphonamides will usually clear up most coliform infections of the urinary tract, some are more resistant and infection by enterococci is totally so, calling for mandelic acid treatment. There is an extensive section on venereal diseases which includes information, based on both laboratory and what may be called field experiments, that sulphonamide compounds are efficient prophylactics against gonorrhoea and chancroid. The sections on wounds and burns are also very full and include detailed instructions for local application. Intestinal infections are discussed under six separate headings, and this section contains much information which is by no means common knowledge. Among diseases noted more briefly are those in which sulphonamide treatment serves only to control secondary bacterial infection, and various less familiar or imperfectly studied conditions: the attitude to the treatment of anthrax is perhaps unduly sceptical. In a full account of toxic reactions it is said of the prevention of urinary obstruction by acetyl compounds that the daily urinary output should be maintained at not less than 1,500 c.cm. This sensible and moderate caution should be well heeded. Fluids are often forced to such an extent in order to prevent this complication that therapeutic effect is greatly impaired—it is of no use to give large doses of the drug if steps are also taken to secure elimination of maximum rapidity. An appendix gives methods for estimating sulphonamide concentrations in the blood, for testing the sulphonamide sensitivity of bacteria, and for sterilizing sulphanilamide powder.

or local application. The Medical Research Council is to be congratulated on producing another memorandum of great practical value, with perhaps a wider field of usefulness than any of its predecessors.

PAVLOVIAN PHYSIOLOGY AND WAR NEUROSIS

Front-line experience of psychological breakdown has not hitherto bulked largely in the literature of war medicine. A paper by Love¹ on his experiences at Tobruk is therefore especially interesting, the more so because in spite of its isolation from books in the field he attempts certain theoretical formulations which are of a suggestive kind. It is notable that the number sent back to their units in what is described as "good or fair shape" is only 44%. This is less than half the percentage claimed by such observers as Gordon Holmes and William Brown in their experiences in the last war. What may be the significance of the difference from the results described by such an unexpected twin constellation of authorities raises tantalizing conjectures. Love remarks that age as a factor is of importance, those individuals who are over 35 at the time of their breakdown being less apt to return to duty. The now well-recognized fact that psychological predisposition accounts for a good deal is again illustrated in the observations that 12.7% had had a previous nervous breakdown, and 21% some other form of psychological disability before the war. With Tobruk under bombardment treatment was limited by the resources obtainable to such extent as was possible, with sedation and encouragement, and occupational and physical training. The advantages of group activity were apparent; but so also were the disadvantages of association with a certain proportion of individuals who had lost control over their fear. It was regarded as of special importance to obtain enough sleep by means of whatever sedatives were available. This must have been one of the most difficult situations in which psychiatric treatment has ever been carried out.

In regard to prevention, Love emphasizes the importance of the regimental medical officer and the need for educating all Service doctors in psychiatric matters. On the theoretical side his suggestions are interesting. He recognizes, what all Service doctors have to recognize, that there is a constitutionally timid type of man, but it is especially his analogies from Pavlovian physiology that are worthy of notice, although there is a deceptive ease with which such analogies can be applied. Thus the conception of fear as a reflex is adopted, and the increasing susceptibility to fear is spoken of by Love as due to a facilitation of this reflex with resultant spread to more and more stimuli; while, on the other hand, in the sounder type of man the fear "reflex" is regarded as inhibited as the result of experience—or, in Pavlovian language, as the individual's cortex analyses the stimuli. Two other analogies from Pavlovian physiology are adduced. Love suggests that the prolonged attempt at inhibition of fear ultimately led to a neurosis, just as in the Pavlovian dog an attempt at prolonged inhibition may end ultimately in failure, with the appearance of so-called neurotic symptoms in the dog. Fine differentiation of stimuli, as Pavlov demonstrated, produces the same result. Such analogies are certainly seductive. Delayed inhibition, for example, might conceivably correspond with the latent period so often seen in the development of a neurosis in a frightening experience. The author himself, however, is very cautious in advancing these suggestions. The well-known fact that experience of a trying kind may be followed

by an emotional reaction when any reminder of the original experience occurs is more scientifically stated in the terms of association psychology than of conditioned reflexes.

Human beings, unlike Pavlovian dogs, are not concerned with sensations like sounds to be differentiated, or with reactions to feeding stimuli—i.e., to stimuli on the physiological level—so much as with ideas and meanings in social situations, with which prestige, self-esteem, and so on, are closely bound up. Nor in human beings are the stimuli immediate; they are more often representational. Pavlov himself, in an obscure passage on war neuroses, seemed to recognize this when he spoke of fear producing certain physiological symptoms, which in "weak people" last for some time, thus "freeing them from the necessity of endangering their lives." He speaks also of such people as "excluding the influence of other representations which might oppose the representation of the conditioned desirability of these symptoms." "Conditioned desirability" is surely a question-begging notion. Many of the Pavlovian physiological notions, as Schilder and others have pointed out, are concepts rather than observed phenomena, and allow nothing for mental "sets": that shifting in attitude, coming about sometimes only after a prolonged moral struggle, which changes a timid creature into a brave man—a result often brought about by the example of someone else, or by any one of the numerous factors included in the term "morale."

The author speaks of the association with a group of others as a process of "deconditioning"; but it is something a good deal more subtle than is represented by this dangerously attractive word. The application of Pavlovian physiological principles to social phenomena reaches its zenith of absurdity in the master himself when he cites the Christian martyrs as proof of the power of auto-suggestion, with the explanation of their behaviour as "the effect of the concentrated excitation of a definite area of the cortex accompanied by marked inhibition of the rest of the cortex." This may be good physiology, but as a contribution to all-round understanding of life this kind of wild analogy is a step backward into the materialistic abyss. Love is more than an appetite, and a war neurosis more than a stimulation of the fear "reflex."

CONTINUOUS CAUDAL ANAESTHESIA IN OBSTETRICS

It is all but 100 years since Sir J. Y. Simpson attempted by anaesthesia to abolish the pains of labour. His method was good but not ideal, and to this day search goes on for methods that are easier, safer, and more certain. The latest is caudal anaesthesia—that is, the injection of a local anaesthetic into the cavity of the sacrum. The injection is extradural, but fluid so introduced will infiltrate to surprisingly high levels, so that the roots of the lumbar and even the dorsal nerves may be anaesthetized. Caudal, or sacral, anaesthesia is by no means new: it has for many years been used for various surgical purposes. From time to time it has been advocated in obstetrics, notably by Pool,¹ who in 1941 published results of a full investigation of this method. He found that with novocain (procaine) results were too fleeting to be of value in obstetrics, but on changing to a solution of nupercaine (then called percaïne) in saline he obtained analgesia of satisfactory duration. Caudal anaesthesia in obstetrics is at present being tried enthusiastically in many clinics in the U.S.A. Hingson and Edwards² found that the disadvantage of the relatively brief duration of anaesthesia could be overcome by repeating the injections at short intervals. A special

¹ *Med. J. Austral.*, 1942, 2, 137.

¹ *J. Obstet. Gynaec. Brit. Emp.*, 1941, 48, 84.

² *J. Amer. med. Ass.*, 1943, 121, 225.

malleable needle is passed into the sacral hiatus and is allowed to remain in position throughout labour. Normally the dural sac does not extend lower than the second segment of the sacrum, but in exceptional cases it may extend further, thus constituting a danger, for injection of a large quantity of an anaesthetic drug into the cerebrospinal fluid may be followed by grave or even fatal results. After insertion, suction is applied with a syringe to determine whether the dura has been entered. If cerebrospinal fluid is not obtained, an apparatus is then connected by means of which injections can be given repeatedly without further disturbance to the patient. It has been found that the most suitable anaesthetic substance is metycaine—gamma-(2-methyl-piperidino)-propyl benzoate hydrochloride (Eli Lilly and Co.). This is used in 1.5% solution, and not more than 8 c.cm. is at first injected in order to test the patient's tolerance. If all is well a further 22 c.cm. is then injected, and this dose is repeated at 45-minute intervals, depending upon the effect obtained. The authors report the results achieved in 589 cases. Usually pain was relieved in about 10 minutes. The injections were repeated over periods averaging 7 hours, the longest being 30 hours. No serious disadvantages are mentioned, and it is stated that forceps delivery, breech delivery, perineal incision and repair, could all be carried out without additional anaesthetic. Gready and Hesseltine³ also report a series of 22 cases dealt with by this method. Satisfactory anaesthesia was obtained in all but three. In one case the patient, after the initial injection, went into a state of collapse for 30 minutes. More recently Gluck and Rochberg⁴ report a series of 35 cases in which procaine (novocain) 1% solution was used for continuous caudal anaesthesia. They preferred to give the injection by a continuous drip method, following the technique used for blood transfusion. Complete relief of labour pain was attained in all cases. The forceps rate was high, but it is stated that the operation was in most cases "elective." In one case symptoms were severe. The patient lost the power of speech and later collapsed. Artificial respiration was required for 45 minutes, after which recovery took place, and 10 hours later the patient was delivered of a living child. These workers also report that during the puerperium the patients often complained of severe backache, and in one or two cases they "may have developed a neuritis." The earlier report by Gready and Hesseltine also mentions two cases of severe pain in the back and legs "after the drug wore off."

From these reports it is clear that caudal anaesthesia is effective in relieving the pains of labour. In cases observed in this country the striking feature has been the rapid change in the patient's appearance and mental condition, so that a woman wearied with labour and making "heavy going" in the second stage exclaims with relief when she finds that her suffering is lifted. Although reports are conflicting, it seems probable that labour is lengthened for the reason that spontaneous bearing-down efforts are absent or at least diminished. But the chief deterrents to the wide use of caudal anaesthesia are the possibility of sudden collapse and the fear of remote sequels. Despite precautions, the drug may be inadvertently injected into the cerebrospinal fluid, and even if this is avoided individual susceptibility to anaesthetic drugs cannot be foretold. Finally, it is a sobering thought that serious damage—even meningitis—may result from the introduction of septic organisms into the sacral canal. The procedure requires skill and experience, and throughout treatment the patients must be kept under constant supervision by a trained anaesthetist. Nevertheless, in suitable cases

and in suitable surroundings caudal anaesthesia relieves the pain of labour, and should be considered for patients who are approaching mental or physical exhaustion and in whom it is necessary to allow labour to continue for several more hours before delivery can be safely effected.

THE HAEMATOLOGIST'S HERBAL

Shakespeare tells us that when Antony was defeated and driven starving from Modena, "his palate then did delight the roughest berry, on the rudest hedge." We too have had to make use of the natural fruits of the countryside in this time of drug shortage, for some of them are rich in vitamins. The Vegetable Drug Committee of the Ministry of Supply, with the co-operation of 47 county committees and an army of voluntary workers, attacked the hedgerows with such vigour last year that a total of 46 tons of rose hips was collected. This should be a valuable addition to the country's store of antiscorbutics, for the rose hip rivals the blackcurrant as a source of vitamin C.

The rose hip was also one of the original sources of the capillary permeability factor, vitamin P, which has more recently been shown to be present in high concentration in blackcurrants.¹ It would be idle to pretend that we have any clear idea yet of the significance of vitamin P in health and disease. While it seems now to be agreed that the capillary-resistance test is of no value in assessing the state of vitamin C nutrition, and that the test is rarely positive in fully developed scurvy,² the action of vitamin P on the capillaries remains disputed. A recent report suggests that, whereas vitamin P modifies the effects of negative pressure on the capillaries, it does not influence the effect of positive pressure.³ The negative-pressure test has been successfully applied to the guinea-pig as a method of biological assay of vitamin P.⁴ A new outlook on the vitamin is offered by the report⁵ that it occurs in the tissues of the plant in combination with a protein, as part of a tissue enzyme system, a chalcone-protein complex. A chalcone is an unsaturated aromatic ketone, and the hesperidin chalcone of vitamin P is a member of that class of naturally occurring substances capable of being reversibly oxidized and reduced. The chalcone-protein complex is easily reduced by sodium thiosulphate and re-oxidized by oxygen, and it can also act as a hydrogen transporter. It is possible that vitamin P is concerned with the mechanism of hydrogen transportation and energy production in animal tissues as well as in plants. We can say, then, that natural antiscorbutics, which usually contain vitamin C as well as C, are plus a little something which the synthetic vitamin C hasn't got, and which may well be a therapeutic advantage.

Yet another natural source of antihæmorrhagic material is now suggested. The berry of the mountain ash, *Sorbus aucuparia*, has been used as a spring tonic by the Laplanders for many years. The United States Dispensary describes the *Sorbus* fruit as having been used for scurvy and American workers⁶ report that it contains appreciable amounts of ascorbic acid and manifests vitamin K activity. They also suggest that it is of value in the medical treatment of cholecystitis. The claim for vitamin K activity is well supported. The evidence that it relieves the symptoms of chronic cholecystitis is less convincing, as the effects on the symptoms of indigestion were not adequately controlled. Another proposed addition to the haematologist's herbal is shepherd's purse, *Bursa pastoris*, extracts of which have

been reported by Copley and Lalich⁷ to produce improvement in haemophilia when given by injection. Similar claims have been made by Hecht⁸ on behalf of a proprietary herbal extract which is administered by injection. It is known, however, that both sodium citrate⁹ and oxalic acid¹⁰ increase the coagulability of the blood when given parenterally, apparently by making the prothrombin more reactive. Haemostatic effects from injection of plant extracts must therefore be assumed to be due to the oxalic acid they contain unless the contrary is proved, and in any event such effects are much less important in time of war than those of natural antiscorbutics which can be given by mouth.

FOOD AND HEALTH OF ESKIMOS AND LAPPS

Eskimos of Northern Greenland, protected by the Danish administration from harsh contact with civilization, still lead a primitive existence. Their diet, entirely carnivorous, consists of the flesh, glandular organs, and often entrails, usually eaten raw, of Arctic mammals, birds, and fish. Their life of great physical activity, in which privations and extraordinary feats of strength and endurance are taken as a matter of course, testifies to the adequacy of this diet, and medical evidence¹¹ has demonstrated the absence of scurvy and rickets and no increased tendency to vascular and renal disease. The Labrador Eskimos, who have more dealings with whites, have largely abandoned their primitive methods of existence: dried potatoes, flour, tinned goods, cereals, and cereal products form a considerable part of their diet. Their meat is cooked, and, though Labrador is not truly Arctic, vegetables cannot be grown. As a result, scurvy, rickets, and a combination of the two are universal and severe.¹¹

Interesting information has recently come to hand about the health and food habits of another primitive northern race, the Lapps. These people, whose origin is still obscure, number now some 30,000. They are found in Norway, Sweden, Finland, and Russia, and are chiefly engaged in reindeer raising. A large proportion of the Swedish Lapps have retained the old nomadic habits. These Lapps were originally mainly carnivorous, and reindeer flesh was the chief constituent of their diet. The meat was eaten boiled: liver, heart, kidneys, and bone marrow were boiled for a very short time; blood was usually consumed raw. Reindeer milk was freely taken. Birds, birds' eggs, and fish were also eaten. The bark of young green pines, fresh shoots of spruce and pine, and various herbs, roots, and berries were eaten, and birch sap was drunk in the spring. The fare has now changed a good deal. There has been a transition from the old intensive method of reindeer raising to the extensive. The animals are now mainly looked upon as slaughter animals, and milking has been almost entirely abandoned. Home consumption of reindeer meat and offal has declined, as more is sold or given to dogs. Sausage and tinned meat are purchased instead, and some cow's milk is used. Rye bread, wheat flour, cereals, and potatoes form now an important part of the diet, and coffee and sugar are taken in relatively large quantities. Ekvall¹² reports that some 50% of the Swedish Lapp children have rickets, and he noticed after-effects of rickets in some adults. He observed no cases of manifest scurvy but many indications of the latent disease. Severe caries is common in young adults, but old Lapps have better teeth, and the Lapps are unanimous in the opinion that caries has increased of late. There is no hemeralopia, but conjunctivitis, probably caused by smoke

in the huts, is not unusual. Neuralgic myalgia is common in old and young, and arthritis deformans was noticed, but Ekvall found no acute or chronic rheumatic polyarthritis in nomadic Lapps, neither had any nomads been treated for this disease in the last ten years at Umea Hospital, though some settled Lapps had been admitted. This may not be unconnected with the small incidence of catarrhal infections of the air passages, tonsillitis, or pneumonia. Tuberculosis is no more prevalent among the Lapps than among the rest of the population, and Ekvall saw no organic disease due to valvular trouble, no nephritis, no pernicious anaemia, and no diabetes mellitus. Dyspeptic troubles and neuroses with depressive features are not uncommon. In the old days of barter, spirit drinking used to be very prevalent among Lapps, but the religious revival in the second half of the nineteenth century put a stop to it and alcoholism is no longer a menace.

Nevertheless, the fact remains that the diet of these people is not now what it should be, and the observations of Thomas and of Ekvall show how easily can the delicately poised balance of an exclusively or predominantly carnivorous diet be upset. In high latitudes the danger of scurvy is ever present; raw skin, liver, and flesh of Arctic animals, and, further south, odds and ends of the sparse vegetation, are the only natural antiscorbutics. Also, unless fish is taken freely by the mothers and given to children from an early age rickets is bound to occur. These primitive people can live off the land in health and vigour, but their diet does not easily lend itself to dilution with the energy foods of civilized man.

RESPIRATORY FUNCTION OF THE DIGESTIVE TRACT

In a paper on the respiratory function of the digestive tract¹ J. G. Dillon reaches some conclusions which are of medico-legal importance. From x-ray studies he concludes that air enters the stomach and intestines of the newborn and adults during the inspiratory movements of the thorax, and that swallowed air has no substantial significance. The opening of the oesophagus into the stomach depends not on an oesophageal sphincter but on the sphincter-like action of the diaphragm at this point. The muscular and tendinous prolongations of the diaphragm form a typical pinch-cock, which allows food to enter on expiration. According to several observers a negative pressure is produced in the oesophagus and in the stomach by inspiration, and this draws in air. Thus everyone has a gastric respiration as well as pulmonary respiration, and the presence of air in the digestive tract of a newborn child can serve as a proof of extra-uterine respiration and hence as evidence that the infant was born alive. The x-ray examination of a stillborn foetus at any time of its uterine life never reveals any traces of air in the digestive tract, but that of a dead foetus which has breathed after birth, even for a very short time, always discloses the presence of air in the stomach and intestines. Even when the lungs are not expanded after birth by a short-lasting effort at respiration air will be found in the digestive tract. An efficient x-ray examination is, then, a most reliable and sensitive test of a foetus having been born alive and affords documentary evidence. Dillon states that air which is loudly eructated by adults has not been swallowed but has been drawn into the stomach by inspiration: the term "aerophagy," he claims, should then be replaced by "gastro-spury." Ventriiloquists, as is known, use the stomach as an aerial reservoir; it is filled with air by inspiration and emptied during speech. An invalid whose larynx has been destroyed by cancer learns to use this manner of speech.

BRITISH SURGEONS' VISIT TO U.S.S.R.

IMPRESSIONS OF SOVIET MEDICAL ORGANIZATION

The four British surgeons who have been paying a three-weeks visit to Soviet Russia attended a reception given in their honour by the British Council immediately upon their return, and gave the assembled company some account of their experiences. This British mission was sponsored jointly by the British Council and the Medical Research Council, and its members were Surg. Rear-Adm. G. Gordon-Taylor, consulting surgeon to the Royal Navy; Mr. E. Rock Carling, consultant adviser to the Ministry of Health, the Ministry of Home Security, and the Ministry of Pensions; Major-Gen. D. C. Monro, consulting surgeon to the British Army (War Office); and Mr. R. W. Watson-Jones, civilian consultant in orthopaedic surgery to the Royal Air Force. Two American surgeons, Lieut.-Col. Elliott and Lieut.-Col. Loyal Davis, and a Canadian surgeon, Prof. Wilder Penfield, accompanied them.

The visitors during their short stay in Russia inspected hospital arrangements as far forward as Vyazma on the Western front, visited the clearing, field, and mobile hospitals, and inspected the medical institutes and depots in Moscow. They found the organization of Russian medical services excellent. In their surgical work the Soviet medical service, with some differences in detail, follows the same general principles as those accepted in British war surgery, and has reached the same conclusions. The Commissar in charge of the service stated that at the time of the last war the Russians realized that their arrangements were not as good as those of their allies, and during the twenty-five years between the two wars they have set themselves to reach a standard of medical and surgical work which will bear comparison with that of any other belligerent country.

Two Impressive Organizations

Two points impressed the mission very greatly. One was the system of blood transfusion, which is carried out on a colossal scale. The arrangements for the collection of blood are beyond criticism, and the number of voluntary donors is very large. In one institution in Moscow a daily average of 500 to 800 donors are bled, and 90% of them are women. No woman is allowed to be bled more than seven times a year, but in practice, so large is the number of volunteers, they are not bled more than five times. They receive extra rations and also payment, but four-fifths of the money received is returned for war purposes. The same procedure is followed as in this country in the use of plasma and serum. In no circumstances has the Russian Army lacked transfusion blood. The blood is transported to the front by large aeroplanes and then to outlying parts by small aeroplanes. At one place on the front blood has actually been flown to small collections of wounded behind the German lines. The second point was the organization for getting special cases into the hands of specialists at the earliest possible moment and in the condition in which they liked to receive them. Even as near to the front as eight or ten kilometres the different kinds of cases according to the nature and location of the injury are segregated and passed in the hands of junior specialists, who, after early treatment, pass them on to their seniors at the special hospitals. There appears to have been no shortage of dressings or anaesthetics. The Russians rely almost entirely on local and spinal anaesthesia.

Training of Personnel

As for the medical personnel, the chief of the medical services of the Russian Army, General Smirnov, is 35 years of age, and an expert opinion on him given by an academician was that he not only was an admirable administrator but was held in the highest regard by his colleagues from the professional point of view. The medical service is becoming a woman's service; 90% of the doctors now under training are women, as compared with 50% in peacetime. The mission noted that some of the young women doctors carried as many as five wound stripes, which meant, not that they had received five wounds, but that they had been wounded five times. For doctors in Russia the ordinary course before the first State qualification is five years, comparable with our own require-

ment. It takes three years to get a bachelorship and three more years to get a doctor's degree. Nurses had three years' training before the war, and this is now reduced to two years.

The Russian nurse evoked the great admiration of the visitors. Not only is she excellent at the job for which she has been trained, but she can turn her hands in spare time to any employment, even to building hospitals, involving cutting down trees, squaring timber, making window and door frames, digging out foundations. She is specially expert in the art of camouflage. One of the members of the mission described how their car stopped at a place in the forest where, apparently no building was in sight. Slowly it dawned upon them that they stood at the entrance to a 1,000-bed hospital so camouflaged as to appear part of the forest itself. Some of the trees had even been left standing inside the building, their tops growing out of the roof.

The visitors made as extensive an inspection as was possible during their brief stay, and only shortness of time prevented them from going to the Far East, where the convalescent cases are sent. They saw something of the research institutes and medical organization in Moscow, where the civil defence and ambulance arrangements impressed them. Five telephone operators are detailed every night to deal with emergency medical or surgical calls from any part of the city, and within two minutes of the receipt of the call a well-equipped ambulance, with doctor, nurse, and orderly, is on its way. In the control room there is an immense map of Moscow; on receipt of a call a button is pressed for the name of the street, and the street then appears illuminated on the map, and the nearest ambulance station and the quickest route are at once indicated.

It is hoped that a return visit of Soviet surgeons to this country will be arranged.

THE MASS RADIOGRAPHY SCHEME

A conference of the National Association for the Prevention of Tuberculosis was held in London on July 28 and brought together a very large assembly of delegates from all parts of the country. It was addressed by Mr. ERNEST BROWN, Minister of Health, who said that the attack on pulmonary tuberculosis had been intensified by the introduction of mass miniature radiography and by the new scheme of allowances for persons undergoing approved treatment for pulmonary tuberculosis. The total cost of the two schemes when in full swing would be about £3,000,000 a year, and by the end of September thirty-four county councils and fifty-five other authorities would have adopted the family allowances scheme.

Introducing the subject of mass radiography Wing Commander R. R. TRAILL said that it had been proved that this system made it possible to discover the disease before it reached dangerous proportions or destroyed the reserve line of natural resistance. When more apparatus was available it would be possible to make a periodical review of the supposedly healthy at those ages at which they were specially liable to develop the disease. Surgeon Commander FRIZPATRICK gave an account of the system as adopted since 1939 in the Royal Navy. It was possible to examine 600 cases a day with one apparatus. Dr. P. M. D'ARCY HART mentioned a survey of 15,000 people engaged in industry. Arrangements for mass radiography among civilians must differ from those for Service personnel inasmuch as the examination was on a voluntary basis. In factories the co-operation of the management must be obtained and the shop stewards instructed.

Dr. F. R. G. HEAF (assistant medical officer, L.C.C.) referred to the need for prosecuting the examination and relieving any anxiety on the part of the individual without at the same time setting up an invalid neurosis. In the case of persons who had to undergo sanatorium treatment he suggested the adoption of the prophylactic workshop scheme, which had had considerable success in Russia.

Co-operation with General Practitioners

Dr. C. H. C. TOUSSAINT (clinical tuberculosis officer, Bermondsey) said that it was wrong to suppose that tuberculous persons did not seek advice. Many of those who were referred to the tuberculosis officer would be found to have been visiting their own doctor, off and on, for perhaps a year. It was important to enlist the full co-operation of the general practitioner if the scheme was to have its full value. He described what he in Bermondsey and his colleague, Dr. E. K. Pritchard, in Southwark had done by investigating,

ith the help of the general practitioners of the district, groups of persons who had been complaining of minor symptoms. Among these, of course, there was a much higher proportion of chest abnormalities of all sorts as well as a higher proportion of cases of active tuberculosis than among the examinees in general. Dr. RITCHARD said that the results of this work in Bermondsey and Southwark had been encouraging, and no difficulty had been experienced in co-operation. In view of the fact that tuberculosis still carried with it a certain social stigma he thought it a pity that the scheme should have been announced simply as a means of discovering tuberculosis, because this might act in some cases as a deterrent to those who would otherwise seek examination. It should have been presented as a means of discovering in addition to tuberculosis other chest conditions which needed urgent treatment.

Dr. PETER KERLEY, who wound up the discussion, mentioned some opposition to mass radiography. One argument advanced against it was lack of mobility of the apparatus, but in fact the apparatus was quite easily moved from place to place, and he did not think it could be made more mobile than it was at present. Objection had been made to mass radiography on the ground that there would be a spate of wrong diagnoses and thus a condition of "tuberculosis neurosis" would be encouraged. But, in fact, the diagnostic technique with the new films was far superior to that which went with many of the large x-ray films taken in this country to-day. He suggested that part of the E.M.S. organization might be turned over to deal with early tuberculous cases.

FUTURE OF THE VOLUNTARY HOSPITALS

Some timely observations on the part played by voluntary hospitals in our national life were made by the DUKE of GLOUCESTER when he presided (for the first time) at the recent annual meeting of the King Edward's Hospital Fund for London. Referring to the discussions now taking place on the future of hospital services, he said that voluntary hospitals afforded an opportunity to many thousands of people to take a practical and personal interest in the welfare of the patients, whether by voluntary contributions in money or kind, by contributory schemes or works funds, or by service ungrudgingly given on committees and boards of management. Voluntary activities such as these, which lifted the individual out of the sphere of his or her own personal interests and offered a means of service to the community, should be encouraged and preserved. They were part and parcel of the democratic structure of society, and upon their interaction with the official provision through the State and local authorities depended the power of the whole system to grow and adapt itself to changing conceptions of the public need. On the medical side there were the important elements of freedom and elasticity. Central supervision and co-ordination should leave room for those whose ideas might not immediately commend themselves to those in authority. The Duke recalled the opposition to Lord Lister and other innovators in their day, and wondered whether the opposition would have been insurmountable under a hospital system conforming too closely to an established scheme. Voluntary hospitals, he continued, did afford that most essential element of freedom, and it would be sad if in our anxiety to achieve other objectives this precious thing were to disappear. In the meanwhile the Fund was helping the Ministry of Health to collect the data necessary for its survey of the hospital services.

Among other matters to which the Duke referred was the appointment of Prof. J. C. Drummond as chairman of a special committee to give advice and assistance on diet to any hospitals seeking such help. The Distribution Committee of the Fund has prepared a memorandum on the supervision of nurses' health. This and an investigation of hospital diets (hospital feeding affects nurses as well as patients) reflect the Fund's interest in the welfare of nurses. Finally, the Duke announced that Dr. H. Morley Fletcher had been appointed chairman of the Nursing Recruitment Committee in succession to Lord Luke, and Dr. A. M. H. Gray to be a member of the Distribution Committee.

Lord Dawson on Present Plans

LORD DAWSON OF PEN said that the medical service must be run by those who understood it—doctors, nurses, hospitals—who must have a primary say in what the design of the service should be. To pull down the whole structure of medicine and in the course of two years to rebuild it would

be a disaster. There were a number of people in this country who conscientiously held views which would amount to the uprooting of that structure. The foundations could be built now, and the chief of those foundations was the hospital service. The Minister of Health had altered his reference since the scheme was first launched. It originally concerned hospital service—at least that was the impression of the public—but the aim now was a health service. This meant—what many had wanted for years—the bringing together of preventive and curative medicine; not only in every hospital but in the education of medical students. It would need two years to work out and lay down the foundations of this great scheme, which meant also the bringing together of municipal or local government hospitals with voluntary hospitals in agreed areas. Those areas had yet to be determined, and, when determined, each should have a key hospital. One of the difficulties was that probably from a constitutional point of view the ultimate administrative authority had to be something in local government. A large body of skilled people spent their whole lives studying the cure and prevention of disease, and care should be taken that they were not placed under a lay committee not necessarily experienced in hospital affairs. The idea of the voluntary hospitals was to provide an advisory council at the elbow of each local authority and make it statutory for the local authority to consult with that body on all questions of policy.

Mr. ERNEST BROWN, Minister of Health, who was also present at the meeting, said that the confidential discussions on the future health and hospital services had ended. The next phase would be the presentation of a White Paper. This was necessary if the public was to understand all that they wanted to do for the nation and to be assured that it was being done in the right way. After adequate discussion in Parliament and in the country on the basis of the survey and the White Paper, it would be for the Government to make up its mind what form legislation should take. He thanked the King's Fund for all the help it had given in discussions with him.

SURVEYS OF HOSPITAL SERVICES

At the recent quarterly meeting of the Regionalization Council of the Nuffield Provincial Hospitals Trust a report was received on the surveys of hospital services in provincial areas which the Trust, as the agent of the Ministry of Health, is organizing and financing. The Trust has organized surveys for the major portion of the country, and is directly associated with those in seven areas. Two surveys are being undertaken by the Ministry of Health—the London and the North-Western areas. Hospital services in South Wales are being surveyed by the Welsh Board of Health. The surveyors appointed by the Trust are:

North-Eastern, Sir Hugh Lett, Dr. A. E. Quine. *Yorkshire*, Sir H. L. Eason, Dr. R. Veitch Clark, Mr. W. H. Harper. *Eastern*, Sir William Savage, Mr. C. H. S. Frankau, Sir Basil Gibson. *Birmingham/West Midlands*, Mr. J. B. Hunter, Dr. R. Veitch Clark, Sir Ernest Hart. *Berks, Bucks, and Oxon*, Prof. G. E. Gask, Prof. R. H. Parry, Mr. E. C. Bevers. *Sheffield/East Midlands*, Prof. L. G. Parsons, Dr. G. E. Godber, Mr. S. Clayton Fryers. *South-Western*, Mr. V. Z. Cope, Dr. W. J. Gill, Mr. A. H. Griffiths. *South Wales and Monmouthshire*, Prof. J. A. Nixon, Prof. R. M. F. Picken, Dr. A. T. Jones.

A survey is to be undertaken in Northern Ireland and will follow the main lines of those in England but will include mental hospitals and mental deficiency institutions as well. The surveyors are: Lieut.-General Sir William MacArthur, Dr. Stanley Barnes, Dr. Duncan G. Leys.

The council had before it suggestions for the establishment of Group Preliminary Training Schools for Nurses, and it decided to recommend the Trustees to consider financial support which will be available for the development of such training schools. The council was advised that, with the substantial financial assistance of the Trust, regional health and sickness bureaux have been established in the Berks, Bucks, and Oxon and Glos areas. It is hoped that the bureau in the Berks, Bucks, and Oxon area may be accommodated in the Institute of Social Medicine at Oxford, and that it will be under the immediate direction of Prof. J. A. Ryle, Director of the Institute. In Glasgow a subcommittee has been formed with a view to starting the scheme in the North-West sector of the city, which includes the Western Infirmary and the Stobhill Hospital. The University is to provide accommodation for records, and the public health department to help with tabulating the data.

Reports of Societies

LIGHT AND VISION

LIGHT AND VISION

After the annual general meeting of the Illuminating Engineering Society Sir JOHN PARSONS, F.R.S., F.R.C.S., gave an address on light and vision. In his opening remarks he recalled his presence at the inaugural dinner of the Society in 1909, and the recognition of the founder, Mr. Leon Gaster, that the aims of the Society were not limited to physical problems, but involved physiological, psychological, and aesthetic factors. At that time there was little guidance on lighting matters from the medical side, but engineers had themselves few data, and instruments for measuring illumination were primitive and cumbersome. The first paper read to the Society in 1910 was given by Sir John Parsons on the subject of glare, and the Society had since been preoccupied with this and similar problems involving vision. Sir John next discussed the relation between illumination and visual acuity, drawing attention to the valuable work of Dr. Lythgoe and others and the development of the Illuminating Engineering Society's Code. Research had established the great importance of background and adequate contrast. It was interesting to note that in the early days of the Society a limit of 100 to 1 for the ratio of brightness of object and background was proposed. Turning to the colour of light Sir John expressed the view that there was no evidence that artificial sources of light, he injurious effects of ultra-violet light in everyday life had been grossly exaggerated, though the recent development of fluorescent discharge lamps had substantial advantages. Much of the latter part of the address was devoted to vision at low illuminations, the peculiar appearance of colours in weak light, and the conditions determining the perception of objects at the very low illuminations now experienced in the streets in wartime. Sir John referred at some length to the work of the Departmental Committee on Lighting in Factories and Workshops and to the fact that legislation on factory lighting, recommended before the last war, had been enacted only during the present one. The requirements for adequate lighting in factories had now been incorporated in the Factory Act, and this might serve as a precedent for the future, when lighting conditions in schools, offices, etc., might likewise be defined and standardized. The recognition of the I.E.S. Code during the war had been largely due to the fact that it was ready when needed. Now, therefore, was the time to complete codes and specifications relating to other fields of lighting. The address ended with a brief reference to the problems awaiting the Society in connexion with post-war lighting, in which again the study of vision would be found to play an important part.

Psychiatrists of the U.S.A. have recently

Psychiatrists of the U.S.A. and Canadian Forces in this country were recently entertained by the London County Council at Sutton Emergency Hospital. Short papers were read as follows: Minski on "Rehabilitation of the Neurotic," Col. Petrie on "Psychopathic Personalities," Dr. Slater on "The Recognition of the Neurotic in the Services," and Dr. Sargent on "Physical Treatment in Psychiatry." A luncheon was held at which the following were present: Mr. Salmon, Clerk of the L.C.C.; Dr. W. Allen Daley, Medical Officer of Health; Prof. Francis Fraser, Director-General of the Emergency Medical Services; Dr. O'Brien of the Rockefeller Foundation; the administrative officer of the Mental Health Services; Mr. R. Sargood, chairman of the Mental Health Services Committee, and other members of that committee. The afternoon was devoted to a demonstration and talk on the electro-encephalogram by Dr. Hill, visits to the occupational workshops and a talk by Dr. Shaw, and a demonstration of electroconvulsive therapy by Dr. Sands. Col. Thompson and Col. Van Nostrand, on behalf of the U.S.A. and Canadian psychiatrists, thanked the Council and medical staff for having given them such a successful and interesting day.

In observing the acute effects of smoking on respiration and circulation, R. J. Main (*Proc. Soc. exp. Biol.*, N.Y., 1941, 48, 495) came to the conclusion that the smoking of one cigarette "according to a standardized exaggerated technique lowers alveolar CO₂ for from 10 to 30 minutes and increases blood pressure and heart rate or from 30 to 60 minutes in both smokers and relative non-smokers."

The Teaching of Ophthalmology

The Teaching of Ophthalmology.—The lamentations over the alleged values which found expression at the Congress (*Journal*, July 31, p. 144) may be regarded as a large part of clinical ophthalmology rather than of surgery, and that the correct education is therefore to be found on the curriculum. The first introduction to the subject, provided in the preliminary class, is physiology, where the student learns the anatomy of the eyeball and of the ophthalmoscope and the several parts of the visual field to the visual pathway. This foundation affords the opportunity of application in the field of ophthalmology where the systematic use of the ophthalmometer, and of the methods of testing the visual acuity, can be included in the collection of clinical data, necessary to the establishment of a diagnostic conclusion.

In principle, this curriculum should be taught by the ophthalmologist, and not by the surgeon.

In principle, this cultivation of medical ophthalmology, urged by no less an authority than the late Sir C. W. Ogle, who, in his book, *The Use of the Ophthalmoscope*, published in 1871, maintained that "every medical school should teach the use of the ophthalmoscope as carefully as it teaches the use of the stethoscope." That careful teaching is essential to the application of the stethoscope in every clinical case, and is enforced by the ease with which the skill in the use of this modern instrument is attained. If the claim is granted that the sanction of an examination test, and if examination in the use of the stethoscope is made a condition of graduation in medicine, will apply this test I have found from personal experience that the student world will rise to the occasion. There remains the need for instruction in the estimation and correction of errors of refraction, in operative methods in the recognition and treatment of local diseases of the eye and its related parts; and this is the department of ophthalmology and surgery. While fully recognizing these local claims, and the skill which deals with them, it is none the less true that the pathological conditions of the visual apparatus are part of a general or remote disease picture, and the contribution these conditions make to the values of ophthalmology are secured by making the clinical investigation of visual conditions not the property of a special department but a part of the natural and necessary part of the art of clinical medicine in general practice.—I am, etc.,
Hove.

C. O. HAWTHORNE

Childhood Infection and Later Pulmonary Tuberculosis

SIR.—I was greatly interested in the account given of the work of the Brompton Hospital Research Department under this title (July 24, p. 98). It is a work of first-class importance and a form of investigation which has been too long neglected. The only comparable investigation is that on blood by Davidson in Edinburgh. While an immense amount of literature has been written about definite disease, very little work has been done to determine what is the real normal and how far can the alleged normal vary within the limits of good health.

In 1929 I published an article on the subject of "Hilus Tuberculosis" in the *British Medical Journal*.

In 1929 I published an article in the *B.M.J.* under the title: "Hilus Tuberculosis as an Important Causative Factor in Pulmonary Tuberculosis in Adults." The titles of the two papers have a close similarity, and although the conclusions arrived at do not exactly correspond to mine, they go much further in that direction than any I have seen so far. My conclusions were:

"(1) Hilus tuberculosis can be a causative factor in the development of a large, extensive, and fatal variety within the limits of good

(1) Hilus tuberculosis can be demonstrated clinically in a relatively large percentage of children. (2) In spite of much clinical evidence suggesting pulmonary tuberculosis in children actual invasion of the lung parenchyma is relatively rare. . . . (4) Pressure from enlarged bronchial glands can be demonstrated clinically; it has the effect either of restricting the free flow of air into a lung or of interfering with the free flow of air into a lung or of the blood in the lungs, and

ing rise to localized areas of oedema, rarely to general pulmonary edema. (5) Rupture of adherent caseous glands into a bronchial tree is a not uncommon cause of pulmonary tuberculosis.

"The diminished death rate from pulmonary tuberculosis is probably due mainly to the lessened risk of infection from 'open cases' in the homes and to the more prompt recognition of early cases. It is unlikely that a further appreciable decrease will occur unless a serious attempt is made to deal with the large number of potential cases *before, not after*, the lung parenchyma has been invaded by the dreaded tubercle bacilli."

These conclusions were arrived at as the result of a clinical search extending over a period of ten years and involving re-examination and re-examination of 20,000 children. The facilities at my disposal were very limited compared with those available to the Brompton Hospital Research Department, but my conclusions arrived at are approximately similar to mine. For example, the article states: "Certain immediate and later implications may, however, arise, as a rule secondarily to the involvement of lymphatic glands in the primary complex," according to Parrot's law, "there is in the child, whose organs are immature and considerably better adapted for such investigations than an adult's, no affection of the lungs which would not be also present in the adjoining lymphatic glands; and, vice versa, there would be no change in the tracheo-bronchial lymphatic glands without analogous ones in the lung."

The exhaustive work of Ghon has proved that an initial primary lesion is common in children, and also that this lesion almost invariably heals but the bronchial glands are always involved. Here, in my view, lies the potential danger of a recrudescence in adult life. It is too often assumed that the "flare up" in later life is due to the lighting up of an old lesion, whereas it is more likely to be due to the softening and breaking down of an infected bronchial gland, which was adherent to the adjoining pleura in the situation of the newly discovered lesion or emptied itself into a bronchus. I could quote several cases in support of this claim, but space forbids.

How often do we find that a definite pulmonary lesion was preceded by influenza or a bad cold? The fresh infection breaks down the already diseased glands, with the sequence already suggested. I found that evidence of tuberculous infection was more frequently found in those suffering from some epidemic condition of the mouth—decayed teeth, infected tonsils, etc.—and especially in those suffering from defective nutrition. The bronchial glands form the most important barrier against all infections, but in mass infection, particularly when of a virulent character, they fail in their task.

There is, I am afraid, too much complacency about the way we are tackling the problem of pulmonary tuberculosis, and I find no reason to alter the conclusions arrived at fifteen years ago. It is now established that a certain percentage of pulmonary lesions are due to the bovine rather than to the human tubercle bacillus; hence the great need for teaching the public how to sterilize the milk consumed. Milk heated to 70° C. is sufficient, but overboiling does not affect the nutritive value: the vitamins are easily replaceable, as the rearing of babies on boiled milk can readily testify. Here is another field for investigation to counter the opinions of eminent medical men who have no practical experience but who do harm because the public attach as much importance to their intuitive opinions as they do themselves.—I am, etc.,

Birkenhead.

D. J. GARR JOHNSTON.

H 11 for Cancer

SIR.—I should like to report an apparently very successful clinical result of treatment by H 11 for carcinoma:

Male aged 54. He first noticed clinical signs in February, 1940. In February, 1941, treatment by diathermy was given for a large carcinoma of the bladder by Mr. H. O. Robinson. X-ray therapy was given to the residue in the bladder by Mr. Anthony Green in April, 1941. The local growth has remained well from then on. He developed spinal metastases, cervical and lumbar, x-rays taken in September and November, 1941, by Dr. Chesterfield Cooke showing typical changes over an extensive area. For these bony metastases he received x-ray treatment again by Mr. Green in September and November, 1941, and pain was relieved. The erythrocyte sedimentation rate and plasma phosphates were elevated. He then developed a large liver on which there were palpable nodules, jaundice, retching, and ascites, his weight falling to 7 st. He was seen by Mr. H. O. Robinson and Mr. Anthony Green, both of whom diagnosed

secondary deposits in the liver and did not advise x-ray treatment. A course of H 11 extract was started on Jan. 21, 1942, because both surgery and radiotherapy offered no hope whatever. In a month the retching and jaundice had gone, diet began to be normal, and in seven weeks there was no ascites, and weight was over 7½ st. The liver gradually diminished in size and nodules became palpable. In nine weeks the patient began walking unaided; after eighteen weeks he was able to walk a quarter of a mile. Twenty-six weeks after commencing treatment he was back at his office, clinically in good health, and with no certain evidence of active growth. He is still well after a year's work, putting in 5½ long days each week. At the end of treatment he weighed over 9 st. and now weighs about 10 st.

Mr. Anthony Green tells me that he has treated a few further patients without success, but feels that the method might be tested at a research centre because one successful case may be due to the injection of foreign material and does not prove specific action.

When a patient is suffering from cancer and both a surgeon and a radiotherapist can offer no hope whatever, I should like to be advised of a better method of treatment that offers any chance of recovery.—I am, etc.,

Redhill, Surrey.

FREDERICK CURTIS.

SIR.—The publication of H 11 therapy and experimental investigations of it in the *Journal* of July 17 are suggestive of premature conclusions on the part of Gye, Ludford, and Barlow, who have failed to corroborate the Hosa Research Laboratory workers' much more extensive observations, and also suggest a similar biased criticism in the comments of the leading article on the same subject, for one cannot agree that an extension of 12 to 18 months of improved health with recession of malignant growth and absence of secondaries in inoperable and hopeless cases of cancer, as shown by Kidd in 42% of his patients, can be considered other than a very satisfactory and desirable clinical result. The leader also infers that the Hosa Research Group is a business undertaking, but is this also not a mistake? Inquiries have led me to believe that the Hosa Research Laboratories are a philanthropic establishment operating as a registered charitable trust, and therefore, surely, its workers are on similar lines from this point of view to those of the Imperial Cancer Research Fund workers.

As your leading article says, many practitioners throughout the country are using H 11 therapy, with what may broadly be said to be 50% of satisfactory clinical results in inoperable cases of cancer, and it is to be hoped that what almost appears to be an attempt to sabotage the most useful adjuvant medical treatment at present available in inoperable cancer cases will not deter practitioners from employing H 11 therapy under controlled conditions until the Imperial Cancer Research Fund organization, or some other progressive body, provides the profession with a better therapeutic help.

While fully agreeing with the remarks that it is the doctor's "bounden duty to exercise the utmost scientific caution" and to avoid the raising of false hopes, yet we might also remember the statement of a very ancient and profound philosopher, who said that when everything else had failed there still remained faith, hope, and charity, and the greatest of these is charity; and perhaps, in the new world we all look forward to, charity may find a new place in the relationship of even scientific research workers.—I am, etc.,

Southport.

E. CRONIN LOWE.

SIR.—I was very interested to read the reports of H 11 published in the *Journal* of July 17. I had been impressed by the experimental results shown by Mr. Thompson on the inhibition of carcinomatous growths in mice and decided to try the preparation in the treatment of cases which were frankly inoperable.

Early in 1940 we commenced using the preparation; it was known then as G.R.H., and this was used until H 11 was evolved, and one or two modifications of this were thereafter used throughout the treatment of the cases. The cases were selected because of their inoperability or their resistance to radium therapy.

While the series of cases treated here was smaller and the treatment might not have been as intensive or as prolonged as in those cases mentioned by Kidd, in many the treatment

was prolonged to the limit of the patient's tolerance. The majority of the patients very quickly became intolerant of the injections which were carried out twice daily, and as it was considered that the substance was excreted very rapidly trials were made with a repository dose which proved ineffective. The substance was administered here both intramuscularly and intravenously without any apparent difference in its effect. In none of the cases was life prolonged nor did the growth seem to be in any way inhibited.

Tumours which had extended to the surface of the skin, and whose superficial limits were therefore measurable, were selected in at least two instances for this treatment, but again no sign of any attempt at healing or restriction of the extent of the growth was evident. Every one of the patients submitted to this treatment at this hospital died, and I came to the conclusion that, however effective the substance was in the control of the transplant growth in mice, it had no effect clinically. The treatment was therefore discontinued.—I am, etc.,

W. ARKLEY STEEL, M.D., F.R.C.P.,
Medical Director, Hillingdon County Hospital.

Uxbridge, Middlesex.

Diabetic Retinitis

SIR.—Dr. George Graham, in his letter concerning diabetes (July 24, p. 115), remarks that he has "watched the retinitis improve when the diabetic condition has been brought under control." I should be interested to learn whether any of your other readers has had the same happy experience. Among all the cases I have seen of defective vision due to diabetic retinitis, none has ever shown any appreciable restoration, however soon the diabetic condition was brought under control by diet and other measures. Lest my own experience should have been in this respect unusually gloomy, I put the question to half a dozen ophthalmological colleagues, none of whom could ever remember having seen visual improvement in a case whose defective vision was attributable to diabetic retinitis.

I do not for a moment question the validity of Dr. Graham's observations. I only suggest that appreciable improvement in diabetic retinitis must be extremely rare compared with the opposite condition of steadily deteriorating vision from diabetic retinitis that goes on increasing in spite of all known devices for adjusting the victim's disordered metabolism.—I am, etc.,

London, W.I.

J. H. DOGGART.

Globin Insulin

SIR.—The conclusion Dr. R. D. Lawrence records (July 24, p. 103) that the action of globin insulin with zinc is not materially different from that of protamine-zinc-insulin is, as he admits, not in agreement with the opinion of the American workers with this preparation. It may therefore be of interest to your readers to know that laboratory evidence on many hundreds of rabbits agrees with the American workers' view and not with that of Dr. Lawrence. In the Tuckahoe (U.S.A.) laboratories of the Wellcome Foundation work has been in progress for 6 or 7 years, and Mr. R. Thorp, working in the Wellcome Laboratories at Beckenham, amply confirmed the claims of his American colleagues. The table gives his results on 18 groups of 12 rabbits. The blood sugars are given as a percentage of the initial blood sugar.

Hours after Injection:	2	4	6	8	10	12
Blood sugar:						
G.Z.I.	53.4	61.1	73.0	79.9	86.5	90.9
P.Z.I.	61.2	62.6	64.5	67.7	74.3	79.2

At the 2nd hour globin insulin gives a lower blood sugar than protamine insulin ($P=ca\ 0.049$). At the 4th hour they are indistinguishable. At the 6th, 8th, 10th, and 12th hours protamine insulin gives a lower blood sugar than globin insulin ($P=ca\ 0.022, 0.001, 0.03, 0.06$ respectively). Unmodified insulin in similar doses would have practically completed its action by the 6th hour. I am therefore encouraged to believe that the American clinicians' conclusions are more likely to be correct in this case than those of Dr. Lawrence. Nor am I shaken in this belief by his reported experiments. His patient's reaction to any insulin is, I should judge, abnormal, for 32 units of soluble insulin produced very little effect up to the 4th hour, although carbohydrate had been excluded

from the diet, and the maximum fall was at the 10th hour. It is not surprising, therefore, that in this patient the average maximum depression for globin insulin is at the 15th hour and for protamine insulin at the 18th. There is, in addition, corroboration of the striking American observation that globin insulin unit for unit produces more total effect than protamine insulin. The average blood sugar for the four days of observation with globin insulin falls from 268 to 239 in 4 hours, 212 in 6 hours, and finally to 198 in 15 hours, after which it rises slowly. In 34 hours (3 observations) the blood sugar was back to 224. Protamine insulin produced in this patient no significant fall till the 15th hour, the blood sugar being its minimum (180) at the 18th hour, but recovered to 215 in 24 hours. This analysis, of course, from a statistical point of view, is no more adequate than Dr. Lawrence's own deductions from the case; it does emphasize the uncertainty of drawing deductions from such a small body of evidence. I have no doubt, however, that Dr. Lawrence would agree with the last conclusion. But he makes certain observations not connected with the physiological action of globin insulin to which I should like to comment.

1. He states that a new delay insulin should not be introduced without withdrawing the old. There are already two delay insulins on the British market, Hagedorn's original form of protamine insulin without zinc having been issued again by English manufacturers at the urgent request of responsible clinicians when Danish insulin disappeared in 1940. I would suggest that the variability in response of different patients to different kinds of insulin is a good reason for providing a further tool for trial in the difficult case.

2. He says that it will be necessary to administer soluble insulin with it. That is not the experience of the American observers, and he admits that its onset of action is more rapid than that of protamine insulin. Dr. Lawrence's remarks on the subject of excess protamine in protamine insulin with zinc are based in part on a misconception. He speaks as though any excess of protamine in protamine insulin will absorb completely any soluble insulin mixed with it. That is not so, for the affinity of protamine for insulin is comparatively low, and the compound of protamine and insulin obeys the mass law so that the product of the protamine concentration and the insulin concentration is a constant—the solubility constant of protamine insulinate—so that no matter how much excess protamine is present added soluble will remain, in part, in solution. Large excess of protamine will only increase the quantity of insulin necessary to produce the amount of soluble insulin required, and since the mixture has to be titrated for each individual patient small variations such as do occur in protamine content are of little importance. In any case, the amount of protamine is determined by regulations under the Therapeutic Substances Act, and it is useless to blame the manufacturers for the deficiency, if any, of these regulations. All that the manufacturers can do is to ensure so far as possible that the protamine insulin made by each of them is, within the limits of the testing procedure laid down, as nearly as possible identical in quality and quantity of protamine. This end extensive experiments are being carried out in collaboration by the three manufacturers concerned at the present time. It is difficult to say what are the exact chemically equivalent weights of globin and insulin. But since a small reduction in the proportion of globin to insulin leads to a considerable reduction in the prolongation of action, I am sure Dr. Lawrence is sure to find if he adds soluble insulin to globin insulin that the added insulin will have its desired effect in the early stages, provided he makes sufficiently extensive observations to eliminate the gross variability of the patient's response.

3. He objects that the solution is clear on the ground that it will be confused with soluble insulin. There will be a label on the bottle in distinctive bright colours which ought to prevent any responsible person mistaking it for any other kind of insulin. I think it is questionable whether the rate of therapeutic progress should be scaled down to suit the capacity of the untrained assistant. The clear solution has positive advantages. It can be filtered after the mixture is made, which is a manufacturing point of some moment in connexion with the freedom from contamination with organism. Its clarity makes it less easy to contaminate in use; in this connexion it has been reported that cases which were "set

ive" to protamine insulin could take globin insulin without reactions. It is not improbable that the reactions were due to careless technique on the part of the patient leading to minor infections of the protamine insulin which were controlled by the more acid reaction of the globin insulin.

It may also be pointed out that there is a practically inexhaustible source of supply of globin in this country which may yet be of importance in wartime, and globin is more likely to be of constant composition than protamine, which is not always derived from the same species.

Nine months ago I started my attempts to get clinical trials carried out on this product in this country. No adequate series of clinical experiments is yet in sight. That is not the fault of British clinicians. Present conditions of dispersal of facilities are responsible. My view is that the American evidence is sufficient ground for no longer delaying to make globin insulin available to the British diabetic. It will in time automatically find its proper place in therapeutics.—I am, etc.,

Wellcome Physiological Research Laboratories,
Beckenham.

J. TREVAN.

Orthopaedics of "Sentry Go"

SIR.—Evidence of recent date has been adduced upon the potential dangers that may afflict the marching foot of the soldier. Even fracture of a metatarsal bone may occur. Hence any suggestion that can be made with a view to preventing those dangers would be of value, provided it was valid and reasonable. No man with an orthopaedic eye, looking at the march of the sentries outside Buckingham Palace, for example, could fail to notice the possibility of trouble in the methods adopted by those sentries. At the "about turn" each leg is semiflexed at the hip, the knee is semiflexed, and the movement is ended by the severe stamping of the foot on the ground before the "about turn" is completed. This stamping action is a potential danger to the feet: it would aggravate any tendency to varicose veins, if it would not actually induce them, and the jar would be conducted to the head by the spinal column. I would not be surprised to learn that men recently relieved from sentry duty complained of headache in consequence. It is to be hoped that this fantastic and rather ridiculous performance will be stopped.—I am, etc.,

Stammore.

G. LENTHAL CHEATLE.

Selective Action of Vitamin C on the Suprarenals?

SIR.—It has been established that iodine is necessary in the diet for normal thyroid function. It has also been shown that the normal thyroid contains about 15 mg. of iodine—almost all the iodine contained in the body—and, moreover, that the iodine content of the gland can be increased by the administration of iodides.

It seems possible, then, that other endocrines may be affected in a similar manner. For instance, vitamin E appears to have a selective action on the gonads, causing descent of the testes and activity in the ovaries; for this reason it is used in cases of sterility. Vitamin D causes a rise in blood calcium and phosphorus whose metabolism is controlled by the parathyroids. It is therefore probable that the function of the endocrines is dependent on the presence in the blood of certain vitamins or chemical substances, and that these substances have a selective action on a particular endocrine.

Investigating further we find that the only vitamin in any large amount in the human body is vitamin C or ascorbic acid; furthermore it is found in the suprarenals in the greatest quantity. This must have some significance, and I suggest that ascorbic acid may be the chemical substance necessary for normal suprarenal function. If this is the case the ingestion of a suitable amount of ascorbic acid should increase the activity of the suprarenals.

With this idea in mind I took 500 mg. of ascorbic acid on two successive days—a total of 1,000 mg. On the third morning I woke early with boundless energy and a feeling of well-being. The pulse rate was increased and the skin warm and moist, similar effects to stimulation of the sympathetic. All these signs are also present in hyperthyroidism, but the fact that ascorbic acid is found practically only in the suprarenals suggests that it has a selective action on that gland, and that increasing the intake of the vitamin increases the amount in the glands, thus increasing their activity.

Some of the suprarenal functions are: (1) production of adrenaline; (2) control of blood pressure; (3) regulation of blood distribution; (4) control of ionic distribution, particularly sodium and potassium; (5) control of liver glycogen; and (6) possible detoxifying centre for bacteria. It will be seen that the circulation, and therefore the nutrition of every cell in the body, is dependent on proper suprarenal function. If, therefore, ascorbic acid is necessary for normal suprarenal function—and its presence in the gland in such large amount suggests this—it follows that vitamin C is the most vitally important of all the chemical substances in the diet. It cannot be due to chance that vitamin C is found so widely in Nature in fruit, vegetables, and milk.—I am, etc.,

Preston.

W. H. DERHAM.

Psychiatric Treatment in General Hospitals

SIR.—I should like to reply to correspondents whose comments lie within the scope of my article under this heading, leaving out other dimly connected and debatable issues raised. I endeavoured to avoid any but the obvious deductions in the commentary, since I intended the paper to be a report on a "social experiment" (see subtitle) in psychiatric medicine, using methods employed not only in Sutton psychiatric units but by clinicians in numerous mental hospitals. It has been suggested that I have tried to relegate mental hospitals to their former custodial role (Drs. T. P. Rees and W. H. Shepley, June 12, p. 735), as in the concluding part of the paper I left the question, "To what extent can mental hospital services, at present largely organized to meet the maintenance needs of an abundance of chronic patients, be adjusted to secure the confidence of the early recoverable patients, so that this confidence would lead to their early treatment and lessen the incidence of chronicity? . . ."

Some of the reactions expressed demand further emphasis on the fact that the patients discussed are a selected group, mostly selected by other psychiatrists of this hospital who are themselves using a comprehensive scheme of treatment, including psychotherapy, insulin comas, modified insulin therapy, continuous sleep, electrically induced fits, etc., and combinations of the foregoing, according to the requirements of the individual patient. A decline in results was noticed where patients were selected for treatment by psychiatrists without personal experience in the comprehensive application of these methods, even though such psychiatrists undoubtedly had long experience in other directions. It follows that general hospital in-patient psychiatry does not consist of the mere allocation of a ward with a psychiatrist in charge; the latter should be trained in the correct selection and treatment of patients if results are to be worth while and risks minimized. In treatment this applies equally to nursing staff.

There has been no attempt to tackle all and sundry psychiatric states in our unit, and the unfortunate "general hospital versus mental hospital" phrase of Dr. Spencer (July 10, p. 54) therefore does not arise. Only by difference in type can one explain the fact that with essentially similar forms of treatment (Drs. Rees and Shepley) 35 beds in Sutton psychiatric ward admitted and discharged in a year more patients than the whole of Warrlingham Park Mental Hospital, with 849 beds, admitted in the same period, and any psychiatrist who has been fortunate enough to be shown round Warrlingham would admit that it must be one of our most progressive mental hospitals. There is therefore little justification in the argument expressed by some correspondents and considered, as I know, by other psychiatrists, that by the use of general hospital neuro-psychiatric wards the mental hospitals are likely as a general rule to receive fewer recoverable admissions.

Having had the privilege of working in four general and four mental hospitals since qualification I know that generally speaking the type of patient treated at Sutton is unfortunately rarely seen in a mental hospital, and his care has too often devolved on the G.P. If this same type did reach a mental hospital, it was usually when chronic or when an acute flare-up of his condition made such a course imperative. Dr. Crichton-Miller (June 26, p. 800) says that there are selected psychiatric patients best treated without the local supervision required by other types, and at Sutton this is being done.

As regards "stigma," whatever the "actual knowledge" of some correspondents may be in this respect concerning its

growth about the "mental ward," I can only report that after two years we are as little troubled by this difficulty as after the first three months. Perhaps our critics are thinking of observation wards, and it may be that we shall have to wait longer before considering ourselves clear of "stigma" possibilities.

Lastly, I feel that whatever influence these matters have on ourselves as doctors there is no doubt that for patients of selected types it brings specialist psychiatric treatment to a frequently recoverable class who, as the figures quoted above show, do not as a general rule use the facilities mental hospitals provide.—I am, etc.,

Sutton, Surrey.

D. E. SANDS.

SIR,—I do not wish to take up much of your valuable space in replying to the critics of my letter (June 26, p. 800) on this subject. To my mind there is a place for the treatment of psychiatric cases in mental hospitals, psychiatric clinics, and special wards of general hospitals, and it seems a pity to me that at the present time in planning for post-war medicine psychiatrists cannot agree among themselves. There is a section of psychiatrists who do not seem to realize that they will be part of a comprehensive service where the man working in the mental hospital will also take his place in the out-patient clinic and general hospital, while the man working in the latter will also do his share of work in the mental hospital. Team work and continuity of treatment are of more importance in psychiatry than in any other branch of medicine, and the successful treatment of the patient is surely the most important point in connexion with this controversial subject.—I am, etc.,

Emergency Hospital, Sutton.

LOUIS MINSKI.

SIR,—For years the psychiatrists have been telling us, as do Drs. Rees and Shepley (July 24, p. 118), that stigma attaches to mental illness only because general opinion remains unenlightened.

Would these psychiatrists themselves employ as assistants or welcome as sons-in-law persons who had been inmates of mental hospitals? Would they view the development of schizophrenia in their daughters with as little distress as a fractured femur or a ruptured ectopic?

Whatever they tell us, stigma will always attach to mental illness and defect in civilized communities, where success in the struggle for existence depends on mental rather than on physical perfection.—I am, etc.,

G. L. ALEXANDER.

Colonial Medical Service, Gold Coast.

The Cult of Negative Health

SIR,—Two different but related problems are being discussed under the above heading. These are, first, the problem of the desirability of civilization and its amenities, and, secondly, that of the needs of the individual if he is to secure complete health. The confusion between these has once again brought up the old fallacy, voiced by many throughout history, that civilization is bad for man. This belief goes hand in hand with the concept of the "noble savage." An impartial view would, I think, decide that in our civilization the majority live a fuller, longer, and, on the whole, healthier life than they would do under more primitive conditions.

The second problem arises because, despite the benefits of civilization, many people are unhappy, frustrated, hypochondriacal, and mentally ill; but before deciding that the amenities of civilization are the causes of these troubles it would be well to examine the problem more fully. Dr. R. E. Lucas surely gets to the root of the matter when she says that all the "interests and abilities" of the individual must be fully occupied if he is to obtain complete mental and physical health. This fact is brought out again and again by physiological, psychological, neurological, and sociological studies. There are so many references that I shall mention only one—*Human Behaviour* (Goldstein). In brief, we may say that the individual requires to feel himself to be a useful and essential member of the community, with his abilities and interests fully used in his work and leisure. The importance of the first factor was illustrated by the decrease in the so-called minor mental and bodily illnesses which occurred on the outbreak of war and during the "blitz," instead of the expected increase.

The second factor will require tremendous organization and progress before it can be applied universally, but we must all strive towards it. Meanwhile little will be gained by blindly removing and prohibiting modern amenities. Thus one woman may fulfil herself in having a baby every year, while another may be crippled and prevented from living a full life by having even one child. These are obviously extreme examples, but the revival of individual medicine must be applied to the whole of life if everyone is to make the most of his life.—I am, etc.,

Harrogate.

JAMES CAMPBELL.

Sulphonamide Therapy in Tuberculous Empyema

SIR,—In connexion with the article on tuberculous empyema (June 26, p. 792) details of this case may be of interest.

An adult male who had been undergoing pneumothorax treatment for pulmonary tuberculosis at St. Brigid's Sanatorium, County Laoighis, since September, 1941, developed fluid in February, 1942. This recurred, despite aspiration and air replacement, on three occasions, and in July, 1942, was thickly purulent. On this occasion, after removal of 12 oz., 20 c.cm. soluseptasine was instilled into the pleural cavity. This pus showed no organisms on direct smear, but culture on Lowenstein's medium resulted in a profuse growth of tubercle bacilli. In August, 1942, 5 oz. of pus, which was, however, much thinner than on the last occasion, was removed and replaced by 10 c.cm. of soluseptasine, since when the pus has not recurred, and the pneumothorax treatment has since continued without further complications.

This is the only case of tuberculous empyema I have had the opportunity of treating in this manner, but three years ago a case of pneumococcal empyema, in which pus had recurred despite aspiration on three occasions and intensive oral and intravenous sulphonamide therapy, completely subsided after the removal of 10 oz. of pus followed by the injection of 20 c.cm. of soluseptasine intrapleurally.—I am, etc.,

Co. Laoighis.

M. CROWE.

Bovine Tuberculosis in South Africa

SIR,—Dr. Basil F. Sampson's letter (June 5, p. 708) states: "Moreover, surgeons will tell you that the typical non-pulmonary lesions of the disease in humans are not commonly seen by them." If Dr. Sampson will visit this hospital I can show him 75 cases of surgical tuberculosis (mostly tuberculosis of the vertebrae), which is the maximum number of cases for which I have accommodation. He can see a list of names of people, several of whom have been waiting more than two years for admission. In the surrounding districts are many patients with surgical tuberculosis who do not come for treatment because it is widely known that we cannot admit more because of lack of beds. I would go so far as to state that one of the commonest surgical conditions in this area, among Africans, is surgical tuberculosis, due, in my opinion, to widespread malnutrition.—I am, etc.,

Victoria Hospital, Moredale,
Cape Province.

W. C. J. COOPER, F.R.C.S.Ed.

Nurses' Pay and Hours

SIR,—The shortage of nurses was acute even before the war, and there were many complaints that the best type of girl was not coming forward. It was reiterated that improvement would only come when conditions of working, feeding, discipline, and salary were much more reasonable. Several committees have deliberated over the question of salary, and have recommended what they regard as munificent increases. But they are totally inadequate. It is now up to doctors to help the nurses; or are we too busy fighting our own battle?

Under the new recommendations student nurses will receive about £40 the first year. This is less than our parlourmaids receive. Yet the nurses work hours as long and hard as any manual labourer, and often, most unpleasant. It is said that their training is part of their salary, but this is a double benefit for the hospital cannot run without senior trained nurses. Moreover, they study and often have to attend lectures in the three hours of free time they are allowed daily.

The position of the trained nurse is equally ridiculous. A staff nurse, State-registered, after completing three or four years' training and passing her examination, is to receive £10

to £120 a year. At present State-registered Civil Nursing Reserve nurses paid by the Ministry of Health receive £105 a year, plus £65 living-out allowance. This works out at 65s. 6d. a week, whereas the L.P.T.B. are advertising for untrained women to become Underground Railway porters at a salary of 67s. 6d. a week.

Finally, may I point out that the 48-hour week still leaves a long working day, if a day and a half are taken off each week, identical with the old working day, since time taken off for meals is now added to the working hours.—I am, etc.,

London, W.6.

C. W. F. MCKEAN, M.B.

Obituary

SIR BECKWITH WHITEHOUSE, M.S., F.R.C.S.,
F.R.C.O.G., F.A.C.S. (Hon.)

President of the British Medical Association

The sudden death of Sir Beckwith Whitehouse, which took place while he was returning home after the meeting of the Council of the British Medical Association on July 28, was briefly recorded in our last issue. Sir Beckwith appeared to be in his usual health at the meeting, and the last remark he made was a graceful acknowledgment of the action of the Council in nominating him for a second year as President of the Association. He confessed that hitherto his presidential duties had been of the lightest, but he added that if the war

situation developed as favourably as some optimists predicted the duties might more closely approach to those of a peace-time President, even though the usual Annual Meeting in his own city was still out of the question.

Harold Beckwith Whitehouse, who was in his sixty-first year, was a man of the Midlands. He was born at Ocker Hill, Tipton, one of the "iron towns" of Staffordshire, only nine miles from Birmingham, in which city he spent the whole of his professional career.

He went to school at Malvern College, and later took his medical training in London, at St. Thomas's, where he was entrance science scholar in 1901 and William Tite scholar in 1902. He graduated M.B., B.S.Lond. in 1906, gaining in that year the Sutton Sams memorial prize for work in obstetric medicine and diseases of women, thus early declaring his bent. In 1908 he took the M.S. of London University, with honours, and qualified for the gold medal in surgery, and in the same year he became Fellow of the Royal College of Surgeons.

In Birmingham he quietly built up a solid reputation as an obstetrician and gynaecologist. His teaching and expository gifts were also quickly recognized. In 1920 he was Ingleby Lecturer at the University—a lectureship named after an early professor of midwifery at Queen's College and intended for the promotion of obstetric medicine and surgery. In 1924 he was appointed Professor of Midwifery and Diseases of Women, succeeding Thomas Wilson, who had held the chair since 1912. Whitehouse was the third occupant of the combined chair. Before 1910 there was at Birmingham a professor of midwifery and a professor of gynaecology, the first to hold the professorship of gynaecology being Lawson Tait. For nearly twenty years in his academic position Beckwith Whitehouse exercised a marked influence upon gynaecological opinion and practice. He was generally recognized as a careful and most illuminating clinical teacher, and united with this was his skill as an operating surgeon. In all that he did he took the most scrupulous care over detail. He was himself the originator of some surgical procedures, and among his inventions was a caecal retractor for appendectomy, whereby the appendix and

a portion of the caecum was isolated from the peritoneal cavity and the edges of the wound. He was also an eager research worker. The subjects within his specialty in which he took the keenest interest were uterine haemorrhage, its pathology and treatment—which was the theme of his Hunterian Lectures at the Royal College of Surgeons, delivered when he was little more than thirty years of age—and the innervation of the uterus.

Between the medical school, his several hospitals, and his private consulting room Beckwith Whitehouse lived busy days—and often nights—and no doubt the work took its toll. He was honorary gynaecological surgeon to the Birmingham United Hospitals (the General Hospital in Steelhouse Lane and the new Queen Elizabeth Hospital out at Edgbaston), and honorary surgeon to the Maternity Hospital in Loveday Street. In addition he was consultant to a large number of hospitals in the surrounding area—the Lucy Baldwin Maternity Hospital, Hammerwich and Sutton Cottage Hospitals, the Smallwood Hospital, Redditch, the Guest Hospital, Dudley, Walsall and Nuneaton General Hospitals—and to the Worcestershire County Council. The demands of all this work, not only upon his time and skill but upon his sympathy, must have been enormous. He once said that as a gynaecologist he heard an undue proportion of people's domestic worries. Certainly no man could practise this branch of the profession for thirty years, especially in a great industrial area in those Midlands which, according to Belloc, are "sodden and unkind," without being a humanitarian as well as a great physician and surgeon. Lady Baldwin consulted him fifteen years ago as to the usefulness of a maternity hospital for her countryside, and received his characteristically enthusiastic reply, "If you get your hospital going I will come night or day to lend a hand when needed." And, Lady Baldwin has added, "He kept his word, coming over twenty miles, often in the dark, to help save a mother and her baby: he never ceased his interest nor grudged the time spent in this work. He saved many a woman, not only at the time of childbirth but also from the suffering incidental to their sex."

His experience as a consultant also filled him with a great admiration for the family doctors, whom he saw carrying on their work under the shadow of the rolling mills and in the light of the furnaces. His appreciation of these men made him apprehensive of tendencies which seemed to him to threaten the survival of family practice and to portend some system of State medicine. An uncompromising individualist, his individualism was the result of his experience and observation of medical practice carried out often under the hardest and most testing conditions. The things which he saw and felt he could express with clearness and force in such a way as to win the respect even of those who disagreed with his conclusions.

Outside Birmingham he found further scope for his energies. At different times he was examiner in midwifery to the Royal College of Surgeons, the Universities of Sheffield, of Bristol, and of Leeds, and under the Central Midwives Board. For four years he served as a member of the Radium Commission. No one appreciated more the value of radium in the hands of the gynaecologist, but he was well aware of the risks and dangers of its injudicious use, and set these out with his usual care in what he wrote on the subject. In 1929, when the British (now the Royal) College of Obstetricians and Gynaecologists was incorporated, he became a Foundation Fellow, and served as a valued member of its council until 1937. In the early days of that College it owed not a little to his enthusiasm and common sense. Until he became President-Elect of the British Medical Association his voice was not often heard in London, but he was vice-president of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine, and a Fellow of the Medical Society of London, and he had been president of the Midland Obstetrical and Gynaecological Society. In 1933 he visited the United States at the invitation of the American College of Surgeons, and was made an Honorary Fellow of that body; he was also made an Honorary Member of the Canadian Medical Association, to which he gave an address on the menopause. He enriched his experience by frequent visits to Continental clinics and operating theatres, and his own writings and research made him well known beyond the borders of this country.

(Lafayette, Ltd.)

His contributions to the literature of midwifery and gynaecology were mostly in the form of papers in the medical journals, but one noteworthy literary task was his editorship of the fourth edition of Eden and Lockyer's *Gynaecology*, published in 1935. The earlier editions of that standard work were revised by the original authors, but on relinquishing their task they asked Beckwith Whitehouse to accept the responsibilities of editorship. The advances in both the science and the art of gynaecology which had been made during the eight years since the appearance of the third edition made it necessary to rewrite various sections, to add a great deal of new matter, and to rearrange the order in which some of the original matter was presented. One innovation was the inclusion of a discussion of the medical aspects of contraception so far as this was believed to be necessary for the requirements of medical practice, and without entering into the ethical questions involved. It was the new editor's feeling that the inclusion of this subject in a standard gynaecological textbook would be welcomed, and that it would have the advantage of placing the matter in its proper perspective.

Beckwith Whitehouse's career, otherwise devoted to midwifery and gynaecology, was interrupted by service in the first world war. Within a fortnight of the declaration of war in August, 1914, he was in France, where he served as officer-in-charge of the surgical division and surgical specialist to the No. 8 General Hospital, Rouen, and the No. 56 General Hospital, Etaples.

In the central work of the British Medical Association, which he joined soon after qualification, he took no large part, though he was for some years a member of the Consultants and Specialists Group Committee. But his counsel was for many years highly valued in the Birmingham Branch, of which he became president in 1934. It was intended that the Annual Meeting of the Association should be held at Birmingham in 1940, and Beckwith Whitehouse was the choice of his fellows in the locality for nomination as President. Although, by reason of the war, no meeting at Birmingham could take place, he succeeded Dr. Thomas Fraser of Aberdeen as President in 1942, and was nominated for office for a second year. It was the great regret of his colleagues that the war prevented Birmingham from showing what it could do in the way of entertainment and pageantry, and the President from proving his qualities as host. When the B.M.A. last met in Birmingham, in 1911, he held office as secretary of the Section of Obstetrics and Gynaecology, and in 1928 he was vice-president, and in 1936 president, of the same Section.

The inclusion of his name in the list of Coronation honours in 1937 was very welcome to a large circle of friends in the Midlands and far beyond. Beckwith Whitehouse was a very likeable man, a man of broad outlook and gentle tastes. At his home at Edgbaston he indulged, as much as his busy professional life allowed, his love of gardening and botany, entomology, and music. He married in 1909 Miss Madge Rae Griffith, a Birmingham lady, and had two sons and one daughter. Much sympathy is felt for Lady Whitehouse and her family in their sudden bereavement, and with the Birmingham school in the premature loss of one from whom several more years of distinguished service both in the home and in the clinical fields might have been expected.

Dr. SEYMOUR BARLING, F.R.C.S., sends the following personal tribute: The death of Beckwith Whitehouse leaves a gap in many circles in Birmingham and the Midlands; his vigorous and dynamic personality touched life at so many points in public and professional life, all of which he enriched by his enthusiasm and capacity for hard work. His appointment as assistant gynaecological surgeon to the General Hospital in 1908 gave him his first opportunity, and this appointment in the city which had known the brilliance of Lawson Tait served as his inspiration throughout life. He was well fitted to carry forward the development of his specialty, in which formerly manipulative dexterity alone was the hall-mark of distinction, for at this time the fundamental part played by the hormones in the sex cycle and the discovery of radium called for new aptitudes which his scientific training and outlook were quick to seize and develop in the service of his craft. So it was throughout his life: his restless mind was always seeking new ways and new ideas to incorporate into his work and carry it forward.

Beckwith Whitehouse found the ordinary social contacts of life difficult, and concealed a natural shyness of disposition beneath somewhat abrupt manner which made it difficult for his contemporaries, even colleagues whom he knew well, to get beneath the surface. It was quite otherwise with those who as students and residents looked to him for leadership, and some of his happiest moments were associated with his annual gathering of old residents, which, growing in size as the years passed, grew into an informal club. As professor he was clear and explicit in his formal lectures, but was happier in clinical teaching in wards and theatres and happiest of all in the daily contacts of hospital work with dressers and residents. In the club he saw those he had moulded and taught by daily intimate contact, and they found in him a friend and inspiring leader. He was devoted to his patients and they to him, and a busy practice claimed him unremittingly. In spite of this he found time for many activities. For several years he served on the Radium Commission, on which his professional knowledge and scientific training were valuable to advise in the control of the remedy which for a time was threatening to become a danger. His election as President of the British Medical Association in July, 1939, gave him great pleasure and pride, and the knowledge that he had behind him the whole-hearted support of the profession sustained him in supporting a position which necessarily would add much to an overfull life. In October, 1937, he was appointed president of the Birmingham Branch of the British Medical Association, and also in 1940 Acting County Director and Controller. He developed and followed the wartime activities of the British Medical Association with the greatest interest, and in none of his public interests will he be more missed than in the councils of that body.

Beckwith Whitehouse found time throughout a busy professional life for his two hobbies of entomology and gardening, and to last immerse himself in both of them in any spare moments he had. At his beautiful country house he found opportunities both, but it is characteristic of the man that even there practice followed him, and his week-ends were usually partly occupied with consultations and operations at the local hospital. Unknown to most of his friends—even those who saw him daily—he had for some time under the shadow of a possible breakdown unless curtailed his work, but the warning was unheeded. He passed away in the flood-time of his many activities, having given abundant throughout a long and busy life to his friends, his patients, and his profession. As one who knew him well, one feels that he would have preferred it thus had the alternative been the inactivity of invalidism. Deep in his mind, though, was the desire to enjoy a time leisure to indulge in his hobbies in the distant future, never to be achieved, when practice could be put aside and his garden claim him.

We regret to announce the death at Chichester of Dr. A. I. BARFORD, for many years a member of the visiting staff of the Royal West Sussex Hospital and M.O.H. for the City of Chichester. Educated at Wellington College and at St. Bartholomew's Hospital, Arthur Morton Barford qualified as M.R.C.S. in 1888 at the age of 20, obtained the Brussels M.D. with honours in 1897, the Edinburgh D.P.H. in 1904, and was elected F.R.F.P.S. Glasg. in 1918. For some years after qualification he was anaesthetist to the North-West London Hospital and the Throat Hospital in Golden Square. While engaged in general practice at Chichester he specialized in oto-laryngo-logy and was appointed aural surgeon to the Portsmouth and Southern Counties Eye and Ear Hospital, and afterwards in charge of the throat, nose, and ear department of the Royal West Sussex Hospital at Chichester; he also became chief surgeon to the West Sussex Constabulary and a member of the county council. His knowledge of public health administration was recognized by appointment as examiner for the Edinburgh and the Glasgow D.P.H. Dr. Barford joined the B.M.A. twenty years ago.

The death is reported from Suva, Fiji, of Dr. DUNCAN CAMPBELL MACEWAN MACPHERSON, Assistant Director of Medical Services, Fiji and Western Pacific. The only son of Hugh MacPherson, J.P., of Acharacle, Argyllshire, he was born in 1901. He graduated M.B., Ch.B. at the University of Glasgow in 1928, and was senior vice-president of the Glasgow University Medico-Chirurgical Society. After holding resident posts at the Newark General Hospital and the Glasgow Royal Mental Hospital he won a Fellowship in the International Health Division of the Rockefeller Foundation, and worked for a time at the Johns Hopkins University, Baltimore, where he was granted his certificate of public health in 1934, and subsequently obtained the D.T.M. of Liverpool. Entering the Colonial Medical Service, Dr. MacPherson worked as medical officer to the Gilbert and Ellice Islands before being transferred to Suva, where, in addition to his official post as A.D.M.S., he was lecturer in pathology, bacteriology, and forensic medicine at the Central Medical School. He had been a member of the B.M.A. since graduation.

Medico-Legal

APPEAL BY GENERAL MEDICAL COUNCIL DISMISSED

SPACKMAN CASE BEFORE HOUSE OF LORDS

The Meaning of "Due Inquiry"

The House of Lords delivered judgment on August 5 in the appeal of the General Medical Council from the decision of the Court of Appeal in the case of Dr. Eric D. Spackman of Worthing. The appeal was unanimously dismissed with costs. The report of the hearing in the House of Lords appeared in last week's *Journal* (p. 182).

Mr. Charles Harman, K.C., and Mr. Douglas Bartley appeared for the appellants on the instruction of Waterhouse and Co., solicitors, and Mr. Cecil Havers, K.C., and Mr. Henry C. Dickens for the respondent, Dr. Spackman, on the instruction of Hempsons, solicitors, who acted on behalf of the Medical Defence Union.

The LORD CHANCELLOR (Lord Simon), after recounting the facts of the case, which were sufficiently set out in the report of the hearing and also in the reports of the hearing before the Divisional Court and the Court of Appeal, said that it was not disputed that the General Medical Council, in exercising its jurisdiction, was not a judicial body in the ordinary sense: it was a master of its own procedure and was not bound by the strict rules of evidence nor subject to correction by the courts so long as it complied with Section 29 of the Medical Act, 1858. That section distinguished significantly between a case in which the practitioner against whom a complaint was laid had been guilty of felony or misdemeanour and a case in which the allegation of "infamous conduct in any professional respect" was not connected with a criminal conviction. In the former circumstances the decision of the Council was properly based on the fact of the conviction, behind which the practitioner could not properly go; but when the complaint was not connected with a conviction the decision of the Council, if adverse to the practitioner, must be arrived at, in the words of the Act, "after due inquiry"—meaning, of course, due inquiry by the Council.

The question, therefore, was whether the Council in the present case could be regarded as having reached its decision adverse to Dr. Spackman after "due inquiry," when it had refused to hear evidence tendered by the practitioner with a view to showing that he had not been guilty of the infamous conduct alleged, and that the finding of the Divorce Court, before which he appeared as a co-respondent, was wrong. This problem did not arise only in connexion with conclusions reached in divorce. Many other instances of adverse conclusions reached in a court of law might be cited—as, for example, in proceedings for slander, in judgment for the plaintiff in an action for seduction, or in a bastardy order made by a bench of magistrates—which might in certain circumstances lead to a charge against a medical man of infamous conduct in a professional respect. It seemed obvious in these other instances that, while the Council might regard the conclusion reached in the courts as *prima facie* proof of the matter alleged, it must, when making "due inquiry," permit the doctor to challenge the correctness of the conclusion and to call evidence in support of his case. The previous decision was not between the same parties; there was no question of estoppel or of *res judicata*, and while in such cases the decision of the courts might provide the Council with adequate material for its own conclusions if the facts were not challenged, if they were challenged the Council must hear the challenge and give such weight to it as it thought fit.

In the Lord Chancellor's view the same course must be taken if the practitioner challenged the correctness of a finding of adultery by the Divorce Court. The decree of that court provided a strong *prima facie* case which threw a heavy burden on the respondent if he sought to deny the charge, but the charge was not irrefutable. This followed from the wording of Section 29, with its requirement of "due inquiry," which meant that the accused party must be given a fair opportunity

of meeting the accusation. This was not to say that the Council must re-hear the whole case, though, in special circumstances, the recall of a previous witness, in the light of what the accused or his witnesses had said, might be desirable.

That there were special cases in which a finding of adultery by the Divorce Court was not to be treated by the Council as final was shown by the Council's own previous practice for if the further evidence tendered to the Council had been evidence which could not with reasonable diligence have been put before the court, the Council would have heard it. There was really no analogy here with the exceptional cases in which the Court of Appeal admitted further evidence. The Council was not a court of appeal. The rule of the Court of Appeal was based on the view that the time to call evidence was on the occasion of the trial, and that on appeal it was normally too late to do so. In the case of the Council, while the conclusion of the Divorce Court constituted a strong *prima facie* case, the procedure should be followed which was set out in the Council's own standing orders: "The practitioner will then be called upon by the president to state his case, and to produce the evidence in support of it." If it was considered desirable to make the decision of the Divorce Court conclusive, and so prevent the possibility of a second hearing on the question of adultery, Section 29 of the Medical Act must be amended. The appeal would be dismissed with costs.

Lord ATKIN, in agreeing with the Lord Chancellor, said that the conduct alleged against Dr. Spackman

"is conduct from which the public have every claim to be protected, and there would be none more ready to afford protection than the members of the medical profession itself. But it is obvious that the gravity of the charge does not diminish the weight of the evidence necessary to establish it; it increases it. The responsibility therefore thrown upon the General Medical Council in such cases is grave."

The practitioner charged was entitled to a judgment the result of the considered deliberation of his fellow-practitioners. They must therefore hear him and all relevant witnesses. It was true that the judgment of the High Court judge might afford *prima facie* evidence in support of the charge, for the Council was not obliged to hear evidence on oath.

"But the very conception of *prima facie* evidence involves the opportunity of controverting it, and I entertain no doubt at all that the Council is bound, if requested, to hear all the evidence that the practitioner charged brings before it to refute the *prima facie* case made from the previous trial. If this is inconvenient it cannot be helped; it is much more inconvenient that a medical practitioner should be judged guilty of an infamous offence by another than the statutory body. . . .

"Nor do I accept the view put forward on behalf of the Council that it is ill qualified to form an opinion upon such a charge as the present compared with a High Court judge. I can imagine no tribunal better qualified to draw deductions from the proved conduct between a doctor and his female patient than the very experienced body of men, for instance, who sat on the present inquiry."

Lord WRIGHT, who also concurred, said that enormous powers, which might close a man's professional career and ruin him financially and socially, had been vested in the Council by Parliament from a faith both in the members' expertness in regard to that grave issue and in their moral gravity and trustworthiness. Such was the eminence of the Council and so completely representative was it of a great profession, the honour and integrity of which were of the highest importance as matters of public policy.

After a long legal discussion of the Council's rules of procedure, Lord Wright continued:

"I am unable to see the force of the objection urged against hearing the evidence that the Council is not a court of law or equipped with the machinery for ascertaining facts. Parliament has put the duty of inquiry upon it, and it seems to have discharged its duty for the last 85 years. Most of the cases before the Council must involve questions of fact which it has to decide as best it can; it can only be in comparatively rare cases that the cause of complaint is a matter which has been decided in a court of law other than by a conviction for felony, or misdemeanour. The court decision should indeed ease that duty, because the proceedings and judgment of the court at least give the Council *prima facie* evidence which may be for practical purposes unanswerable by the practitioner. But he must surely

Medical Notes in Parliament

Constitution of Appeal Tribunals

Consideration of the Pensions Appeal Tribunal Bill was resumed by the House of Commons in Committee on July 22. Sir WALTER WOMERSLEY moved amendments to implement the new conditions announced in the White Paper which set out alterations in the Royal Warrant. These amendments were accepted.

Sir DONALD SOMERVELL moved an amendment providing that there should be a right of appeal from an interim assessment, and that this right of appeal should arise at the expiry of two years from when the man was notified of the interim assessment. He said these cases were under constant administrative review. Whenever a man complained that his circumstances had been worsened there was a new medical board or examination. Dr. HADEN GUEST asked the number of medical men on a tribunal in the Minister of Pensions' own assessment tribunals. Sir WALTER WOMERSLEY replied that the body was a board, not a tribunal. It always included two medical men at any rate. He would not consent to one. The House agreed to Sir Donald Somervell's amendment.

Sir DONALD then moved an amendment providing that when the appellant or a Minister was dissatisfied with the decision of a tribunal on a point of law an appeal might be allowed to a High Court judge. The amendment was accepted.

On the clause dealing with the constitution of appeal tribunals, the committee rejected a proposal that medical men should be attached to the tribunals as assessors and not as members. It accepted an amendment, moved by Sir HENRY MORRIS-JONES, that the medical referees on the tribunals should be practitioners of not less than seven years' standing. A further amendment was made to provide that a tribunal would have power to show to a man's medical adviser documents about his condition.

The committee stage was completed.

Health of Scottish School Children

Presenting, on July 21, the Education Estimates for Scotland, Mr. TOM JOHNSTON said that owing to the war it was not possible to insist upon the usual routine medical examinations of school children. What examinations had been made showed no deterioration in nutrition. On the contrary there was evidence of actual betterment. Of one-third of the school children of Lanarkshire (26,756), only 42 were shown as suffering from "bad" nutrition—an improvement on the previous year. Renfrew County disclosed only 20 out of 12,655 children suffering from "bad" nutrition; and Ayr County 14 out of 14,256 children. In 1942 boys at age 13 were 2½ lb. heavier and girls at age 15 over 2 lb. heavier than boys and girls of these ages in the 5 years before the outbreak of war. Lice, itch, and skin disease were found among no inconsiderable sections of the population. In Glasgow the local authority was making strenuous efforts to stamp out these body infestations and to foster habits of personal cleanliness and hygiene. At some 17 selected schools it had appointed senior women teachers to supervise operations. The consent of the parents and the interest and co-operation of the child were first secured for treatment, and the results achieved were remarkable. Reports from one school showed:

		Vermineous	Nitty
December, 1940	14%	56%
March, 1941	6%	39%
May, 1941	3.5%	12%

Glasgow Education Authority proposed to develop these arrangements. Girls were the worst offenders in vermin infestation of the head, a reason being the present custom of wearing the hair long.

Diphtheria and Scarlet Fever Incidence and Deaths

Mr. ERNEST BROWN furnished the following tables on July 22. They are for England and Wales:

Year	Notifications	Deaths	
		Under Age 15	Over Age 15
1938	65,008	2,687	174
1939	47,341	1,982	151
1940	46,281	2,300	180
1941	50,797	2,390	251
1942	41,404	1,635	191

Scarlet Fever			
Year	Notifications	Under Age 15	Over Age 15
1938	99,274	237	74
1939	78,101	129	52
1940	65,302	106	48
1941	59,432	88	35
1942	55,054	104	..

Midwives' Salaries

Mr. ERNEST BROWN announced on July 22 that he had accepted the recommendations of the Rushcliffe Committee on Midwives Salaries, and had commended them to local authorities for adoption as from April 1 last. The total annual additional cost was likely to be at least £500,000. In the case of midwives employed in institutional midwifery, the Ministry would make a grant to local authorities and voluntary hospitals of 50% of the additional expenditure incurred. To qualify for this grant an authority must adopt the committee's proposals in full. In the case of midwives employed in the domiciliary service the additional expenditure would be covered by the statutory grant provisions in the Midwives Act of 1936.

Increased Compensation for Workmen

Mr. HERBERT MORRISON on July 28 said the Government had had under consideration the claims put forward for increasing the rates payable under the existing Workmen's Compensation Acts. After discussions with the Trades Union Congress and the British Employers' Confederation it had decided to submit a Bill to Parliament embodying certain increases. These were intended to be of a temporary nature and were without prejudice to the introduction of a revised scheme of workmen's compensation which the Government had under consideration in relation to the Beveridge report. The Bill would be introduced forthwith. If there was a sufficient measure of agreement, it was hoped to take it on an early day after the House resumed after the recess.

Alien Doctors in the Colonies

The Secretary of State for the Colonies stated on July 28 that a shortage of qualified doctors had occurred in some Colonies, mainly as a result of secondments for military service, and a number of Colonial Governments had, under powers conferred by the Emergency Powers (Colonial Defence) Order in Council, extended recognition to alien doctors on lines corresponding generally to those permitting such doctors to practise in this country.

Artificial Insemination

Lord BRABAZON in the House of Lords on July 28 drew attention to the consequences of insemination on livestock and to its possibilities in the human race. In America, in childless marriages where the husband was sterile, there was a great demand that the wife, rather than adopt a child, should be inseminated by an unknown father and should produce a child herself. It was estimated that there were in the United States 10,000 applications of that kind. If the child was to be produced by another father the progeny might be looked upon by the world as legitimate, though the doctor would know it was illegitimate. Care and surveillance were needed of that development. There were women who would like to have children without marrying and without sinning. That development would have to be considered. The lawyers would be interested in the extraordinary experiment of the insemination of a female after the male had died.

Lord GLENTANAR said that not only was the artificial insemination of the female being studied but the process of transplanting the ovum of a female into the uterus of another female was also being experimented with, as also the division of the semen into its male and female elements for the purpose of sex determination. If the last practice became practical, profound sociological results might occur. Viscount BLEDISLOE urged the Government to turn its attention to accelerating the process of supplying animal semen for post-war rehabilitation of agriculture in Europe. Two Government stations—at Cambridge and Reading—had been established for producing semen under careful supervision. Artificial insemination of stock had gone on for several years in Denmark and to some extent in this country in reproduction of thoroughbred horses. The BISHOP of CHICHESTER thought the relationship between the sterile husband and the artificially inseminated wife would be anxious and unhappy. The DUKE of NORFOLK, as Joint Parliamentary Secretary of the Ministry of Agriculture, said the human part of the subject was being closely watched by the Minister of Health, who, if and when it became a live issue in this country, would consult the Lord Chancellor on the legal problems which were raised. The animal side of artificial insemination was started by the Arabs many hundred years ago. They used it with some success in the breeding of horses. Modern methods provided a means of improving livestock in a way hitherto impossible. In-breeding was a danger which came to mind. Strict control of the practice was necessary.

Notes in Brief

It is intended to arrange for the collection of haws as well as rose hins this year; haws have a certain medicinal value.

Medical News

The Chartered Society of Massage and Medical Gymnastics will hold its annual Congress on Friday and Saturday, Sept. 24 and 25, in the Great Hall of B.M.A. House, Tavistock Square. The lectures and demonstrations are open to all medical practitioners. The first day's programme includes lectures by Dr. R. D. Langdale Kelham on "The Preparation of Amputation Stumps for Limb Wearing from the Point of View of the Physiotherapist," by Lieut.-Col. St. J. D. Buxton on "Physiotherapy in the Middle East," and the Founders' lecture by Brigadier F. D. Howitt on "The Widening Horizon." On Saturday morning there will be lectures by Mr. R. Watson-Jones on "Rehabilitation, Physiotherapy, and Orthopaedics," and by Dr. J. L. Livingstone on "The Work of a Chest Unit." In the afternoon there will be demonstrations. Applications for tickets, price 1s. 6d. each lecture to non-members, should be made to the assistant secretary, C.S.M.M.G., Tavistock House, Tavistock Square, W.C.1.

A joint conference on "The Administration of the Health Services," arranged by the Institute of Public Administration and the National Association of Local Government Officers (Metropolitan Area Education Committee), will be held at County Hall, Westminster Bridge, S.E., on Saturday afternoon and Sunday morning, Sept. 11 and 12. The speakers will be: Dr. W. Allen Daley, Medical Officer of Health, L.C.C. (chairman); Prof. R. M. F. Picken, M.B., of the Welsh National School of Medicine; Mr. Norman Wilson, M.A.; Dr. J. A. Scott, Medical Officer of Health, Fulham; and Dr. Charles Hill, Deputy Secretary, British Medical Association. Further details will be announced later.

The Society for Experimental Biology is holding a Conference on Wound Healing at Cambridge from Sept. 22 to 24. The council of the society invites members of the British Medical Association to attend the conference. Papers will be given by both clinical and laboratory workers. Those wishing for further details of the programme, accommodation, etc., should write to Prof. T. A. Bennett Clarke, Department of Botany, University College, Nottingham.

Hull is to have a medical provident fund enabling subscribers with incomes higher than those fixed for the local contributory scheme to provide for hospital and nursing home charges, surgeons' fees, etc. The upper income limits of the fund are £450 for a single person and £550 for a person with one dependant to £750 for a subscriber with three dependants. Details may be obtained from the secretary at the Hull Royal Infirmary.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In England and Wales the notifications of measles fell by 568, and of dysentery by 55—these being the only changes of note during the week.

For the sixth consecutive week the incidence of measles has fallen, the total now being about one-eighth of the spring maximum. In Monmouthshire, Dorset, Surrey, and Glamorganshire there were recorded respectively 101, 65, 59, and 50 fewer cases than in the previous week, but there were 33 more in Montgomeryshire.

The notifications of whooping-cough, which fell by 29 for the whole country, fluctuated widely in the counties. The largest of the local variations were increases in Durham 50, Lancashire 32, and decreases in Warwickshire 61, and Glamorganshire 34, and Staffordshire 30. The county totals for scarlet fever were fairly constant, a drop in Essex of 52 and a rise in Middlesex of 30 being the only variations of note.

The reduction of 55 in the incidence of dysentery was due mainly to the fact that no further cases were recorded from the outbreak in Kent, Easby R.D., where there were 49 cases last week. Although the notification of dysentery remains fairly high, there are no very large centres of infection; Lancashire reported 14 cases, and London 13.

The weekly total of 44 for cerebrospinal fever is the lowest since the end of 1939.

In Scotland a rise in the already high incidence of dysentery was due to increases in existing outbreaks, the cases in West Lothian County mounting from 39 to 50 and in Edinburgh from 12 to 22. The largest of the other outbreaks were Aberdeen 14, and Kincardine County 15. There was a rise in diphtheria in the North-Western area and in Glasgow, where 60 of the 136 cases occurred.

The Week Ending July 31

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,979, whooping-cough 1,896, diphtheria 609, measles 2,262, acute pneumonia 432; cerebrospinal fever 47, dysentery 99, paratyphoid 10, typhoid 13.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended July 24.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1943					1942 (Corresponding Week)

* Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

† Includes puerperal fever for England and Wales and Eire.

‡ Owing to evacuation schemes and other movements of population, birth and death rates for Northern Ireland are no longer available.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1.

ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Secretary of the Journal Board, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proof's are not sent abroad.

ADVERTISEMENTs should be addressed to the Advertisement Manager (Hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be sent to the Secretary.

TELEPHONE NO.—B.M.A. and B.M.J.: EUSTON 2111.

TELEGRAPHIC ADDRESSES—EDITOR, *Antiology* Westcent, London; SECRETARY, *Medicera* Westcent, London.

M.A. SCOTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

ANY QUESTIONS?

Vaccines for Common Cold

Q.—There is apparently evidence that immunity to typhoid may be obtained by the use of oral vaccines. From time to time one also sees it recommended that oral vaccines are effective for protection against the common cold. What is the present expert bacteriological opinion on the value of prophylaxis against the common cold with vaccines (a) injected in the usual way, and (b) taken by mouth?

A.—The "common cold," like "influenza," is probably a convenient term to cover a variety of clinically similar conditions of diverse aetiology in the upper respiratory tract. There is good experimental and epidemiological evidence that a filterable virus is a causal agent of the common cold, but unfortunately this virus is very difficult to grow artificially, so that a vaccine of it—such as is now available for influenza A—cannot be prepared. On the assumption that certain bacteria like the pneumococcus, haemolytic streptococcus, influenza bacillus, and the catarrhalis group are, either primarily or secondarily, causally related to coryzal infection, stock vaccines of these organisms have been prepared and used prophylactically. In controlled trials, both here and in America, these vaccines, given in three or more weekly injections in the autumn, have failed on statistical analysis to reduce the incidence of the common cold.

Regarding the use of oral vaccines, the evidence that they are effective in protecting against typhoid is flimsy; certainly they do not provoke antibody formation to anything like the same extent as subcutaneous injection of T.A.B. vaccine does. And if there is anything in Besredka's idea of local immunity, sprays or inhalations of anticold vaccines would probably be more effective than oral administration. There is thus no scientific support for the belief that anticold vaccines, given prophylactically either by injection or by mouth, will reduce the incidence of colds in, for example, a group of factory workers.

Unilateral Parkinsonism

Q.—Is there any treatment for the relief of tremors in one arm due to Parkinsonism? Benzedrine and hyoscine have not been effective.

A.—It is likely that tremor of one arm of a Parkinsonian type is caused by a lesion of the basal ganglia of one side, unrelated to encephalitis lethargica. Though unilateral tremors do occur in the post-encephalitic syndrome, they are not very common. Putnam in New York has treated many of these patients with some degree of success by unilateral chordeotomy, but the tremor has to be very incapacitating to justify so radical a procedure. His views are summarized in a chapter on the surgical treatment of post-encephalitic symptoms in Neal's *Encephalitis*, 1942. The most successful symptomatic treatment of the tremor is by increasing doses of belladonna. The evidence that the treatment by Bulgarian belladonna, first reported in 1935, is more effective than that by other forms of belladonna has been accepted by many, but really critical comparison between it and other methods of administration do not show any convincing difference in results. Belladonna should certainly be tried, and tried in increasingly large doses, depending upon the patient's tolerance, which varies enormously. The dose, small to begin with, should be increased until there is maximal improvement or until signs of intoxication, such as dryness of the mouth or paralysis of accommodation, occur. After this it should be reduced until the side-effects are not unpleasant or until there is evidence that the tremor is not being controlled. It is quite impos-

sible to state an upper limit for the dose of atropine in these subjects. Kleeman (1929) recommends one minim of 1/2% solution of atropine three times a day, increasing by one minim twice daily until an optimal dose is reached. Care should be taken to see that the patient has not glaucoma, but some will tolerate up to 30 minims a day. It is worth while using stramonium or hyoscine in conjunction with the belladonna.

Mycotic Nails

Q.—Two patients, the mother aged 70, the son aged 42 (in the R.A.M.C.), suffered for two years and four years respectively from mycotic infection of three nails of one hand. They have had all sorts of treatment, including x rays, from specialists in London and the Provinces, but without benefit. The son, now in the Middle East, is told that the heat there is bad for the complaint. Is there any satisfactory treatment?

A.—Long-standing ringworm infection of the nails presents a most difficult therapeutic problem because the nail-plate is an impenetrable barrier to a fungicide. Removal of the infected nails is the obvious preliminary step, and then the matrix should be thoroughly cauterized with phenol liq. and a dressing of iodox containing 10% thymol applied. After a week of this ointment, 2% of dithranol in vaseline should be used until local intolerance indicates a return to iodox or to Whitfield's ointment, and if the nail bed becomes macerated under grease it may be covered with dressings of 2% aqueous gentian violet. A milder fungicidal ointment, paste, or paint should be applied nightly until the nail is fully grown. Unless the nail groove is fully cauterized at the operation and is afterwards packed with iodox a relapse under the new nail-plate is likely to occur. Conservative methods usually fail, and success depends upon the subungual penetration of a potent fungicide to the limits of the infection. This entails a daily excavation beneath the free edge of the affected nails, cutting away the plate when it obstructs progress, and then a careful application of a paint of phenol liq., thymol, and iodine, equal parts of each, applied with a pointed stick so that the liquid fills the subungual space, which is daily extended to receive it. Tincture of iodine or undiluted dettol will serve as less caustic applications.

Liver Extract Intravenously

Q.—Is there any disadvantage or otherwise in giving parenteral liver intravenously for pernicious anaemia? I have several patients under my care with this condition, and they all prefer the intravenous route to the more painful intramuscular one, in spite of the slightly unpleasant reaction—bitter taste in the mouth and marked flushing of face—which follows intravenous injections. I know that the intravenous route is used for the severer cases at the beginning of treatment, but I wonder if it might be excreted rather quickly in this manner.

A.—Most observers are of the opinion that the reactions after intravenous injection of liver are more unpleasant than after intramuscular injection. They comprise chills, febrile reaction, fall in blood pressure, and a greater danger from allergic responses if sensitization occurs. There is no information about the relative rates of excretion.

Lag Sugar Curve

Q.—Two years ago, a lawyer, then aged 46, was rejected for insurance because of glycosuria. A younger brother of his had died of diabetes at the age of 18, and also an uncle at the age of 50. The patient's glucose tolerance curve at the time of rejection was of the "lag storage" type. In the interval up to now he has carried on with his food as usual, and he had a recent glucose tolerance test done which was again of the "lag" type. Am I justified in telling him not to bother with further glucose tolerance tests? What is the cause of this type of curve, and what does it signify? What sort of a prognosis does it carry in a man with such a family history?

A.—A "lag" or "steep" curve means that the stomach empties more rapidly than usual, as happens, for example, after gastroenterostomy, and the sugar reaches the blood stream more quickly than usual. It is probable that the insulin is not released quickly enough and the blood sugar rises to over 230 mg. per 100 c.c.m. blood or so after half an hour, but the supply of insulin is adequate and the blood sugar falls to normal very quickly. The prognosis in uncomplicated cases is excellent, but the patient is just as likely as anyone else, but no more likely, to develop diabetes in the course of time. In this case the strong family history suggests that the patient may develop diabetes sooner or later. It is unnecessary to repeat the sugar tolerance test if the total sugar excreted in the 24 hours on a full carbohydrate diet is estimated once or twice a year. If the output increases the sugar tolerance test should be repeated.

Renal Function Tests

Q.—Can modern renal function tests be used to distinguish between glomerular and tubular damage, and, if so, what is their practical application in clinical medicine? Perhaps a general statement could be given shortly, and the details of the most useful tests be supplied, in another issue of the JOURNAL.

A.—The estimation of the clearances of inulin and diodrast, as shown by Homer Smith in his book *The Physiology of the Kidney* (1937) and in subsequent papers, enables us to determine the rate of glomerular filtration, the renal blood flow, and the amount of functional tubular tissue. The technique requires intravenous infusion, continuous catheterization, and difficult chemical analyses, and is therefore not suitable for use in ordinary routine work. The main clinical application of those tests has been in the study of renal function in conditions such as hypertension, pregnancy, haematemesis, shock, and dehydration. It would probably be fair to say, however, that as a result of these studies there has been a distinct decline in the popularity of less specific tests, such as the urea-concentration and the water-excretion tests, except in so far as they may be used empirically for the determination of prognosis in diseases of the urogenital system. Treatment in renal disease can be adequately controlled by examination of the urine, the blood pressure, and the blood chemistry, without resort to special functional tests.

Tests for Hypogonadism

Q.—How far can one diagnose hypogonadism in male and female by biochemical investigation? For example, I have seen it stated that estimation of the blood cholesterol and of the hormone content of urine can be used as indicators of this condition. Are such tests reliable, and can they be used as a guide to treatment?

A.—Biological investigations are of little help in diagnosing hypogonadism. Estimation of blood cholesterol can be used as an indication of thyroid function, being raised in myxoedema and lowered in thyrotoxicosis. Examination of the hormone content of the urine, however, is helpful, especially in the male. The normal range of androgens expressed as 17-ketosteroids is 3.5 mg. to 15 mg. daily for men. In hypogonadism they may be very low or in the lower range of normal, so that the differentiation from normal is not necessarily absolute. However, patients with psychological impotence usually show normal values for androgens. In the female the question is less easy; the assay of oestrogens is not so well standardized as that of androgens, and the ranges of normal values are not only wide but variable, according to the phase of the cycle.

Doubtful Wassermann

Q.—Recently in a series of cases of blood examinations for a panel of blood donors in a voluntary blood transfusion scheme the Wassermann test in four cases was reported "doubtful"—the readings being +1; +2 weak; +2 strong; +1 weak. Are those bloods unsuitable? In the case marked +2 strong there was a suggestive history of contamination; in none of the others was a history obtainable and family history appeared clear. Do any of these cases indicate, from the Wassermann alone, grounds for instituting treatment?

A.—A "doubtful" result of a Wassermann test means that it was neither negative nor positive and suggests the advisability of further investigation of the patient, both clinical and serological, with a view to excluding or establishing a diagnosis of syphilis. A blood which gives a doubtful reaction should not be used for transfusion, at all events until it is certain that any *Treponemata pallida* which might be present are dead. It is said that these organisms lie if the blood is stored at a low temperature for 48 hours. In none of the cases mentioned does the result of the Wassermann test alone justify the institution of antisyphilitic treatment.

Gonococcal Proctitis

Q.—I have two patients suffering from gonococcal proctitis, which has failed to respond to both sulphapyridine and sulphathiazole. Although acute symptoms have subsided for over a year, bacteriological signs are still positive. Is there any record of sulphaguanidine being effective in these cases? Although apparently highly effective in some *Salmonella* infections, I should be interested to know if it has any effect on the gonococcus.

A.—There is no evidence to hand that sulphaguanidine is effective against the gonococcus, especially when sulphapyridine and sulphathiazole have failed. The cases quoted are very remarkable and raise the suspicion that (a) there was repeated reinfection, possibly from the vagina if the cases were females, or (b) the bacteriological findings were at fault; gonococci are not always easy to find or to exclude, whether by smears or cultures, in specimens taken from the rectum. Sulphadiazine sometimes succeeds where other sulphonamides have failed.

INCOME TAX

Purchase of Books

G. B. is assessed under Schedule E as an assistant. He forwarded a list of books he has bought, and states that the inspector of taxes has refused to allow the cost (£9) as an expense. Is correct?

* There is ground in the strict rule applying to assessments under Schedule E for the inspector's view. That rule restricts the allowance of the expenses of employment to sums expended wholly, exclusively and necessarily "in the performance of the duties" of the employment. It is possible that if it were a condition of G. B.'s employment that he should purchase such books as were necessary to his professional knowledge up to date the inspector might allow deduction, but even then he would probably regard as "capital outlay, therefore as inadmissible, books acquired to form a reference library rather than to keep it up to date.

War-damaged House and Property Tax

"INQUIRER" owns a house which was vacant for 1942-3 and likely to remain vacant for some time. It has "received war damage (£80) and requires £100 for internal and external decorations repairs in order to make it habitable." £40 has been assumed to be his annual income from the house.

* If the furniture has been removed from the house the premises should be claimed as being "empty" and the income accordingly regarded as extinguished for the period from the date of removal. Further, if the condition of disrepair owing to war damage renders the house uninhabitable the premises can be claimed as empty notwithstanding that furniture may remain there—until the defect have been sufficiently remedied as to render the house habitable. We understand that if the house is only partly inhabitable Revenue authorities will allow as regards income tax any proportion of liability which has been applied to payment of local rates.

LETTERS, NOTES, ETC.

Vitamin Therapy in Peptic Ulcer

Dr. J. J. O'MULLANE (London, S.E.2) writes: For seven months I have been prescribing vitamins for peptic ulcer. Treatment in this condition should be: (1) dietetic, (2) medicinal. Diet should be full and should be rich in foods containing the vitamin B₁ complex—i.e., peas, beans, lentils, yeast, or marmite. Medical treatment consists of vitamins A, B, C, and liver extract: 50,000 I.U. of vitamin A per day; one ampoule B₁ (25 mg.) subcutaneously once or twice a day—depending on need—until saturation, a rough index of which is the smell of burnt rubber in the urine; ascorbic acid 400 mg. a day and 2 c.c.m. of heparin forte. With some reservations regarding diet when the condition is acute, in my opinion, should be the treatment for peptic ulcer. Compound vitamin pellets and capsules were first used, the form being as follows: Pellets: A, 2,500; B₁, 160; C, 2; D, 250. Capsules: A, 5,000; B₁, 50; C, 200; B₂, 20; D, 5. Six pellets a day yielded 960 units; six capsules a day yielded B₁ units. The pellets proved to be much more effective than capsules. Some cases did very well; some did not. One of the causes of failure was adherent ulcers to liver or pancreas; five cases were revealed by resection; altogether there were five cases in nine months in one practice. Another cause was faulty technique, insufficient dosage, lack of experience, and lack of proper facilities and amenities in general practice.

Stilboestrol in Petit Mal

Dr. A. MINABAWY (Ilford) writes: I was interested to read of the two cases of petit mal reported (July 17, p. 93). This reminds me of a patient who had the same trouble three years ago. She was treated with luminal and pot. brom. mixture, with no success. When I saw her four months ago I realized the fact that she stated the symptoms one year after the menopause. I gave her stilboestrol and reduced the luminal tablets to two 1/2-gr. tablets a day and am pleased to say that she has had no fits since. Admittedly two cases reported were not exactly the same, but I think that use of stilboestrol in their case is worth trying.

Supply of Prepared Bran

The KELLOGG COMPANY OF GREAT BRITAIN LTD. write: We read with interest the letter of Dr. F. Parkes Weber in the JOURNAL of July 17. We would like to bring to your notice that a decision has been reached by the Government Department concerned that "all-bran" be released from the restrictions of the zoning self relating to other cereal breakfast foods, and the product will therefore be available throughout the country. Supplies are again being distributed in the area affected by zoning without delay.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY AUGUST 21 1943

WAR SURGERY IN THE MIDDLE EAST

BY

R. K. DEBENHAM, O.B.E., M.D., F.R.C.S.

Temporary Lieut.-Col., R.A.M.C.; Officer in Charge of a Surgical Division in a Military Hospital

During the last nine months of 1942 3,279 battle casualties were brought to a military hospital on the lines of communication in the Middle East. All types of casualties were seen, under various and changing conditions, as a result of three different battles.

First, during April and May some 300 battle casualties, including a large proportion of severely ill patients, were received from Tobruk by sea. They had already had hospital treatment, and had been held at Tobruk until fit to travel. Suppurating wounds of all types were seen; battle wounds do not heal by first intention. Secondly, during the month of July alone, 2,287 battle casualties were received from the first battle of El Alamein. They arrived from 12 to 48 hours after being wounded, and the great majority had received no treatment other than the application of the first field dressing. The hospital, in fact, worked as a C.C.S., and continued to do so during the following two months. Thirdly, during the second battle of El Alamein, at the end of October, the conditions were again different, and in two weeks about 500 battle casualties were received, mostly from 36 to 48 hours after being wounded. The particular characteristic of this group was that they were selected cases, and for the most part comprised seriously wounded men who were not fit enough for a long journey and who had already received treatment.

These three periods have been particularly instructive, and an attempt is made below to summarize the main features of this diverse group of casualties occurring in men of different colour, different race, and different language. Before dealing with the casualties themselves, a few words about adapting a base hospital to function as a C.C.S. are not out of place.

Hospital Acting as a C.C.S.

As a result of the enemy's rapid advance to El Alamein and the battle that followed, convoys of 100 to 500 men began to arrive daily at the hospital, which now acted as a C.C.S. Convoys almost invariably arrived in the evenings; and an evacuation took place the following morning. The entrance and exit were made as easy as possible, and one-way traffic

TABLE I.—Showing Region of Body hit in 2,287* Casualties from the First Battle of El Alamein in July, 1942

	Cases	Lesions		Cases	Lesions
Scalp and head	165	176	Genitals	4	6
Neck	36	37	Burns	91	130
Face and jaw (incl. M.-F.U.)	44	45	Blast	23	23
Chest	105	110	Mult. abrasions	30	30
Eyes	20	22	Fractures:		
Ears	11	11	Humerus	21	21
Scars	8	8	Forearm	7	7
Abdomen	32	32	Pelvis	8	8
Trunk	221	231	Femur	19	19
Limbs:			Tibia	22	26
Miscellaneous	735	780	Carpus and hand	17	18
Elbow	89	90	Tarsus and foot	12	12
Knee	123	123	Others	3	3
Ankle and foot	236	240	Multiple S.W.	72	72
Hand	97	104	Clavicle	6	6
Buttocks			Total	2,287	2,394

* Excluding 57 casualties admitted to the facio-maxillary unit.

was helpful. Stretcher-bearers became very tired with much carrying, and as many wheeled stretchers as possible were pressed into service.

At first sight one may imagine that a convoy from a battle consists exclusively of wounded men. This is not so. Out of 7,952 troops who arrived at the hospital during the heavy fighting of July, only 2,287 were battle casualties. Table I shows the parts of the body which were hit. The remaining 5,665 consisted of cases medically sick (especially enteritis and malaria), also an assortment of skin conditions, superficial suppurative lesions, piles, sore feet, cases of anxiety neurosis, and the counterpart in less-educated troops—viz., self-inflicted wounds. All these cases had to be rapidly sorted out. The surgical cases were divided into major and minor, which when stairs had to be surmounted often became synonymous with lying and walking. After admission a large reception ward was invaluable. A surgeon or an experienced medical officer with a sound knowledge of surgery acted as sorter, and decided what was necessary for each case. He was assisted by the transfusion officer, who treated shocked patients. A drink of tea was provided as soon as possible and antitetanic serum and morphine were given as required. Cases were written up by the sorting officer for theatre, x ray, or both. Coloured indicators placed at the end of the bed were a great help. These coloured tabs or bands were useful for theatre (blue), x ray (pink), special priority (blue with red cross), and operation completed (red). It is most important that surgery in a shocked patient should be done as soon as the shock has been adequately treated, otherwise his condition will deteriorate again.

A common source of delay in the theatre was waiting for patients. This can be avoided by having an adequate number of stretcher-bearers, and one intelligent orderly in charge of movement control. It is his job to see that there are always patients ready waiting in the anteroom to be taken into the theatre as soon as required. The operating surgeons often saw the patient for the first time in the anteroom, together with the wet x-ray film and report. The number of operations that can usefully be carried on at one time depends not only on the number of surgeons available but on anaesthetists, theatre staff, instruments, etc. Two surgeons working at two tables all night from 9 p.m. to 9 a.m. usually managed 50 cases between them, and during the month of July 1,004 cases went through the theatre. Much time is saved in minor cases by placing the patient and the stretcher on the operating table; this avoids much moving about. A table laid out with sterile instruments on the cafeteria system is also useful; each operating table can then be fed with the necessary tools as required.

For the usual type of wound only the minimum of instruments is necessary, since so much of the treatment depends on proper cleaning up and proper immobilization, and not on heroic cutting. Much of the value of good work is lost if concise notes are not written on the field medical card at the end of the operation. A convoy will be going out in the morning, and most patients should be written up for evacuation as soon as the operation is completed. Under these circum-

stances it is easy to see why no plasters should be skin-tight unless they are also split. A skin-tight plaster is only permissible if the surgeon who has applied it can keep it under his personal observation for a few days, and in busy periods this is out of the question. With a quick turnover all sorts of points need attention. For instance, at the end of the first night's operating we were left with a bowl full of false teeth: fortunately the owners were found before the convoy was dispatched. Incidentally, don't put dentures in dettol; they are out of sight and may get lost.

The Wounds in General

It is a point of cardinal importance that all wounds dealt with have been a result of fighting in dry sandy desert. The problem is quite different from that presented in the last war, in Flanders, where surgeons had to contend with highly manured wet mud. Secondly, the amount of clothing worn was very small, and only rarely was clothing found in a wound. Thirdly, sulphanilamide was used either by mouth or locally in the wound, or both, and this apparently greatly prolongs the time which may be allowed to elapse between wounding and surgical intervention. Prophylactic sulphanilamide technique in the Middle East has now been standardized as follows: Locally, 10 g. into the wound and another 10 g. after operation; by mouth, 5 tablets (2.5 g.) at 6 a.m. and 6 p.m. daily for 4 days. The dosage is printed on a ration card label, and is ticked off as given. The method is simple and works well. The greatest number of wounds were caused by fragments of H.E. shell, mine, grenade, or bomb.

Flesh Wounds

By far the largest number of wounds were minor flesh wounds. Patients arrived in July with the first field dressing applied, and a very good dressing it is. Treatment consists primarily in minimizing the infection, and to this end thorough cleansing of the surrounding skin is important, and if facilities permit it is well worth while to spend some time in cleaning the skin with soap and water and shaving off the hairs. Shaving in itself is a very good mechanical way of cleaning. Wide excision has not been found necessary, and a trim is adequate, usually combined with incision of the skin and deep fascia at each end of the wound to assist drainage. A Spencer Wells forceps or a finger is inserted along the track before this has closed up, and in a large number of cases the missile is easily located and removed. A preliminary radiograph shows whether removal of the foreign body is indicated or not. No prolonged search is justifiable. To allow adequate drainage the size of the external wound should bear a definite relation to the depth of the wound. Dead or damaged tissue should be removed even up to 48 hours after wounding. Treatment by trimming merges into establishing adequate drainage.

Sometimes a large wound at the front of the thigh, with a missile lodged in the posterior compartment, is well treated by making a counter-incision posteriorly to allow drainage and prevent the formation of a haematoma. I saw one case of profound toxæmia from gas infection which had developed from a large haematoma of the thigh and had spread to the surrounding muscles. A counter-drain posteriorly and removal of the large fragment would have prevented it. Adequate drainage combined with the usual general treatment cured the patient. Extensive operations for flesh wounds have been unnecessary and meddlesome. Sulphanilamide powder, and plenty of it, is placed in or blown into the wound, and rubbed into a paste with the finger. Enough dressing of gauze and wool should be applied to absorb all discharge. One hopes that the next dressing will not be done too soon, for repeated dressings are not only useless but harmful. One of the values of a plaster cast is that the wound will not be disturbed after proper treatment. Careful immobilization with plaster slabs or casts is of the very greatest value.

Fascia comes into its own in wartime; it determines the spread of infection. Sometimes a tense swollen thigh, due to a haematoma, requires decompression by longitudinal incision of the fascia lata and evacuation of the clot. The same thing occurs in the forearm: for example, an Indian soldier had a clean through-and-through bullet wound of the forearm; the track passed right through between the two

bones; the forearm was tense and swollen, the radial pi obliterated, and the fingers cold. A long incision was made through the tight constricting fascia. The space was decompressed and the circulation re-established.

In war wounds no sutures should be used, and no pad unless it is necessary to control haemorrhage. Drainage-tubes are quite unnecessary, and in one case at least caused secondary haemorrhage from pressure on the popliteal artery. The best initial drainage is obtained by a good honest through skin and fascia. A transverse cut across the fascia lata is often useful in addition to the usual longitudinal incision. Either the wound can be left widely open or a piece of rubber glove or a strip of vaselined gauze may be laid in the wound to keep it open. It is essential to see that the drain does not act as a cork and so prevent instead of assisting drainage.

Fractures

In forward areas another part of the body is often only splint available: e.g., one leg is tied to the other arm is bandaged to the side; morphine gr. 1/4 to 1/2 comes in the splinting. For fractures of the femur and wounds in and around the knee-joint the "Tobruk" plaster is excellent. Strapping extension is applied to the skin below the knee. Elastoplast extension strapping is much better than the ordinary strapping. It is kept in place by a bandage from above downwards. A posterior plaster slab is applied from mid-thigh to beyond the toes. A pad behind the heel prevents pressure on the toes, and a pad behind the knee gives comfort. A Thomas splint is applied and strapping extension (2 cords) is tied over the end. The splints supplied always have rings which are too big for the average limb, in order that they may be used for all sizes of patients; it is therefore necessary to put a large pad of wool, or the patient's underclothing, between the ring and the great trochanter to make the ring fit snugly. The pad is kept in place by a bandage; this is most important because pads have a tendency to shift during transportation. Finally a pad is placed in front of the knee and one or two plaster bandages are applied over the whole leg and splint to keep the apparatus firm. The site of the wound and fracture is drawn on the plaster with a copying-pencil; the surgeon initials it and records the date. If the plaster is a temporary one for transport only, and the wound has not received attention, this fact should be indicated in large letters on the plaster.

For wounds of the leg with fracture of the tibia and fibula an ordinary plaster is applied, mid-thigh to beyond the toes, with a pad behind the heel. It must be either split or padded anteriorly. If the plaster is to be split it is a great convenience to place a long piece of 1/2-in. rubber tubing smeared with vaseline on the antero-external (fleshy) part of the leg before applying the circumferential plaster bandages. It is pulled out after the plaster has set, leaving a gutter along which the cast can be easily cut with shears. Alternatively a strip of linoleum can be used, and a sharp knife to cut down on it, but the tubing is simpler. In cases complicated by nerve lesions special care is needed to avoid pressure sores.

For wounds of the arm with fracture of the humerus Böhler "U" with padding over the shoulder and over the internal epicondyle is excellent. A collar-and-cuff bandage applied and the upper arm fixed to the side with one or two flannellette or preferably plaster bandages round the chest wall. Fractures of the forearm are conveniently treated with anterior and posterior plaster slabs, from mid-humerus to knuckles, and kept in place by ordinary cotton bandage. A sling is necessary.

Head Wounds

A common injury is a small penetrating wound of the head just under the side of the helmet. The patient may feel a look well, the wound may appear small and be readily missed, yet a fragment of shell may be lodged in the brain. A radiograph shows the hole in the skull, usually less than 1/2 in. in diameter, with comet-like fragments of bone passing inward. Treatment is essentially that of trying to get the wound healed by first intention and so prevent escape of C.S.F. The onset of meningitis. After thorough shaving, the wound is narrowly excised and enlarged at either end in a listerian manner. The mastoid self-retaining retractor is most useful to get a view of the hole. Loose fragments of bone

removed. It is often impossible to close the dura. On but our occasions (out of about 25 penetrating wounds) was the oreign body removed, and then only when it was easily accessible near the surface. The wound is powdered with sulphamilamide and the scalp is closed in two layers, preferably with fine silk sutures; a small glove drain is inserted through the stab wound, or through the extremity of the incision, to drain the subaponeurotic space. When transport was available patients were evacuated to the head centre. The good blood supply and consequent good healing properties of the scalp must have saved many lives, and several of these patients have now returned to duty.

Neck Wounds

It was remarkable how important structures in the neck apparently escaped injury. One patient sustained a wound of the oesophagus. Gastrostomy saved his life. Another had a wound perforating the carotid artery and jugular vein. He developed a traumatic false aneurysm (pulsating haematoma) which gradually enlarged and displaced the trachea to the opposite side. It was left as long as possible before any surgery was attempted, to allow the collateral circulation to establish itself. Finally surgery became imperative owing to pressure on the trachea. Under intratracheal anaesthesia, and with a pre-operative blood drip transfusion, the haematoma was opened, the proximal and distal ends of the common carotid artery compressed, and the rent in the artery and vein were easily seen. Both were ligatured. Unfortunately the patient developed severe pneumonia and had to be propped up in bed. Complete hemiplegia (probably due to thrombosis) developed 48 hours after operation; however, the hemiplegia cleared up and the patient recovered completely.

In one case of perforating wound of the neck the cervical sympathetic cord was involved, as shown by a typical Horner's syndrome; the patient was otherwise quite well.

Chest Wounds

Among the 500 battle casualties from the second battle of El Alamein, 65 suffered from wounds penetrating the pleural cavity. Contrary to what one would expect, these patients travelled very well. Remarkably little surgery was required after arrival at hospital, certainly in the early stages. Two cases were taken to the theatre for the arrest of haemorrhage, and one for closing a sucking wound. Most of the small sucking wounds were well treated by a vaselined gauze pad to close the wound, and a piece of elastoplast or a few silk-worm-gut sutures to keep it in place. The treatment required was almost entirely medical, and was carried out by the medical specialist. Patients were propped up, and in many cases the haemothorax required aspirating on one or more occasions. A few developed empyemata, which were drained by closed under-water intercostal drainage. When fit to travel they were transferred to the chest centre, under the care of Major Logan, R.A.M.C., who tells me that all the patients did well except one who died of poliomyelitis. Further surgery was required in several cases, either for draining pus or for removal of foreign bodies when the sepsis had settled down.

Abdominal Cases

Of the 300 cases received from Tobruk 3 had injuries perforating the bowel (one died). Of 2,287 casualties from the first battle of El Alamein 8 received perforating wounds of the gut (3 died).

Among the 500 casualties from the second battle of El Alamein there were 30 perforating thoraco-abdominal or abdominal wounds, including one extensive wound of the sacrum, in which perforation of the rectum had been suspected and colostomy performed. Although in fact the rectum had not been perforated, the colostomy proved valuable in that it saved the large sacral wound from faecal contamination. Twenty-three patients were operated on in forward areas, and 3 in the hospital (see Table II). They can be divided into four groups:

(1) Thoraco-abdominal wounds, of which there were 11, with a mortality of 10. These figures bear out the very serious nature of this type of wound.

(2) Penetrating abdominal wounds with perforation of the bowel, of which there were 11, with a mortality of 2.

TABLE II

Case	Wound	Other Wounds	Hours before Operation	Abdominal Injuries	Operation	Result
1	Abdomino-thoracic	—	48	Spleen; stomach	Splenectomy; stomach sutured	Died 3rd day
2	"	—	72	Spleen; kidney; colon perforated	Splenectomy; nephrectomy	Died 4th day
3	"	+	56	Upper gut, retroperitoneal, pancreas	Drainage	Died 17th day
4	"	—	18	Liver	Nil	Died 3rd day
5	"	++	18	Stomach	Sutured	Died 17th day
6	"	—	35	Liver	Laparotomy	Died 6th day
7	"	—	51	Stomach; spleen	Sutured	Died 7th day
8	"	—	—	Liver	Subdiaphragmatic abscess; drained 13th day	Died 14th day
9	"	+	—	Diaphragmatic hernia; stomach in left pleural cavity	Nil	Died 9th day
10	"	—	—	No abdominal symptoms or signs; severe chest wound	Nil. P.M. showed perforated diaphragm. No gut injury	Died 21st day
11	"	+	10	Stomach and small intestine	Sutured	Recovered
12	Penetrating abdominal	—	7	Small intestine; right kidney	Gut sutured	Died 13th day; sepsis
13	"	—	7	3 small intestine; 2 sigmoid perforated	S.I. sutured; sigmoid exteriorized	Died 10th day; chest and jaundice
14	"	—	17	Stomach; transverse colon (mult.)	Stomach sutured; colon exteriorized	Recovered
15	"	—	9½	Upper small intestine (9 perforated)	Sutured	"
16	"	—	7	Ileum (6 perforated)	"	"
17	"	+	9	Jejunum and ileum (7 perforated)	"	"
18	"	+	8½	Mult. perforations jejunum; 3 perforations ileum	Jejunum resected 9 in.; ileum sutured	"
19	"	—	4½	4 perforations lower ileum; 2 caecum	Ileum sutured; caecostomy	"
20	"	—	40	1 small intestine; 1 sigmoid	S.I. sutured; sigmoid exteriorized	"
21	"	—	5	Ascending colon destroyed	Resection ascending colon; ileocolostomy	"
22	"	—	Under 10	Perforated pelvic colon	Exteriorized	"
23	"	(+)	9	Contusion of small intestine	Laparotomy	"
24	"	—	12	Haemoperitoneum	"	"
25	"	—	36	"	"	"
26	"	—	24	Retroperitoneal haemorrhage in pelvis	"	"
27	"	(+)	7½	Gross protrusion of small intestine	Laparotomy; gut replaced; faecal fistula later	"
28	"	—	7	Buttock and sacral wound	Colostomy for suspected bowel injury; actually bowel intact	"
29	"	(+)	—	T. and T. bullet wound; R.I.F. to left loin; clinically bowel perforation	Nil	"
30	Wound back	—	48	Wound back; foreign body anterior to L.I.	Laparotomy; retroperitoneal haematoma and foreign body removed	Died 3rd day

(3) Other penetrating abdominal wounds without gut perforation: 7 cases, mortality 1.

(4) A single case of through-and-through bullet wound of the abdomen from right iliac fossa to left loin. Clinically, perforation of the gut must have occurred. No operation: recovery.

The most instructive cases are the 11 wounds with bowel perforation. The 9 who recovered owe their lives to 9 different surgeons who were working in forward areas. Operation had been performed as early as possible and the patients had been held in forward areas for from 5 to 16 days. Post-operative intravenous saline drip, continuous gastric suction, and sulphadiazine had been used as a routine. The sulphadiazine had usually been given intraperitoneally by catheter inserted through the wound—10 g. suspended in 50 c.cm. saline at the end of the operation, and repeated if necessary. Small-intestine perforations had been sutured (resection in one). Large-intestine perforations had been exteriorized (resection in one). The cardinal points seemed to be early operation, late evacuation, intravenous saline drip, continuous gastric suction, and sulphadiazine. All this is very difficult with mobile warfare, but was possible when the line of battle was static.

During convalescence two laparotomy wounds burst open and had to be resutured, and one patient developed secondary intestinal obstruction due to a band of adhesions which had to be divided.

Wounds of Buttock, Genito-urinary Organs, Spine

The chief point to remember about buttock wounds is that the missile may have penetrated into the pelvis, so injuring the bowel or bladder. Suppuration in the buttock is very troublesome (especially if it tracks up from a fracture of the upper end of the femur). A few huge open buttock wounds were seen. They responded well to sodium sulphate dressings (12%) and subsequently needed secondary suture or skin grafting. A wound of the buttock in association with a fractured femur is very difficult to treat, because the ring of the Thomas splint comes up against the wound. One case of this type was put in a hip spica plaster cast. This appears to be the best treatment, but the plaster soon gets sodden unless a window can be cut.

A wound of the genitals is likely to involve also the cave of Retzius, the urethra, and perhaps the bladder. The uncomplicated bladder wound does well with suprapubic drainage. One patient had received a wound of his penis, and a piece of his shorts had been driven into the wound near the base of the organ. It had been passed naturally along the urethra and was emerging, rolled up, from the external urinary meatus, from which it was easily picked out. In one instance the membranous urethra had been completely shot away, and a perineal urethra had to be established. He had control of his urine, because the internal sphincter was still functioning, though the external sphincter had been destroyed. Two cases of ureteric fistula were seen, due to wounds in the loin; and I recollect two cases in which the kidney had been removed in forward areas. A wound of the kidney alone is certainly not common.

Wounds of the spine are usually associated with complete paraplegia, and are apt to arrive during rush periods when there is little time to deal with them. In the few cases in which operation was performed it was usually found that pressure on the spinal cord was produced by bone fragments and not by the missile itself. Suprapubic cystostomy is often necessary in these cases.

Vascular Lesions; Amputation

Ligature of a main vessel with extensive damage to the limb distal to it is fraught with grave danger and usually ends with amputation. The subclavian artery was divided in one case and thrombosed in another. Amputation had to be performed through the middle of the upper arm. In the only two cases in which the popliteal artery was ligatured amputation was subsequently required in each. One case of ligature of the femoral artery in Hunter's canal subsequently required amputation, though in a few others the result was quite satisfactory. The result seems to depend to a considerable extent on the damage to the limb itself and the attendant infection; but, apart from this, the conclusion to be drawn is that ligature of the femoral artery is to be preferred

to ligature of the popliteal. Ligature of the tibial vessels has been entirely satisfactory. The accompanying veins have been tied as well as the artery.

In the last group of 500 wounded there were 3 cases of traumatic (false) aneurysm—the right common carotid, the brachial, and the superficial femoral. In order to allow the collateral circulation to develop they were left alone as long as possible (3 to 5 weeks) before operation was performed. Pressure symptoms or rapid increase in size made further delay unjustifiable. At operation much clot was found in each case, and this tended to mask the pulsatile nature of the swelling, which may readily be mistaken for an abscess. In each case a direct attack was made on the aneurysm itself; the haematoma was opened and the vessels tied in the wound, with satisfactory results.

Thirty-two amputations of arm or leg have been performed in the hospital—upper arm 7, forearm 3, thigh 10, below knee 12: five (2 arm, 3 leg) were for gangrene due to arterial lesions; 4 (1 arm and 3 leg) for secondary haemorrhage; 23 for gross trauma and sepsis, one of which (forearm) was for gas gangrene. The chief points concerning amputation are as follows. The limb should not be removed at the site of election, for infection is almost sure to follow. The maximum length of limb should be preserved, because secondary amputation is often necessary. Some form of flap should be fashioned, as guillotine amputation is so painful. The flaps should not be sutured. The best dressing is probably a vaselined gauze pack; sometimes one or two sutures can be inserted to hold the flap in place over the pack. In badly infected cases the flaps are sutured back to the limb itself, thus leaving the stump widely open; secondary suture can be undertaken later. A liberal quantity of sulphanilamide powder is rubbed into a paste on the stump.

Nerve Lesions and Blast Injuries

Lesions of the ulnar and musculospiral nerves are common; the median is less often involved. Musculospiral lesions were not always due to the wound itself, but sometimes due to pressure—e.g. if the limb was allowed to hang over the operating table. External popliteal lesions were also frequent, and occasionally the whole sciatic nerve was paralysed. Special care must be taken to see that plaster casts do not cause pressure sores in these cases, when the skin is insensitive. It is important to look for nerve lesions before the operation is begun.

The only common blast injury was bilateral rupture of the tympanic membrane. The ears must on no account be syringed, for this invites infection. Patients are often badly shaken after blast, but recover in a few days. Only one case of crush syndrome was seen, and this proved fatal.

Burns

The worst cases of burns came from fighting in tanks. In peacetime, tanning the burn is highly satisfactory; but this is not so in war, because the facilities for preliminary cleansing of the burns are unobtainable, and tanning a dirty burn is as harmful as suturing a dirty wound. Moreover, a tank burn needs skilled and careful nursing, which is impossible on lines of communication. Almost all the burns seen during the period under review had been cleaned up more or less then powdered with sulphanilamide and dressed with vaselin gauze. Patients travelled best with plenty of padding, and the case of the limbs a light well-padded plaster-of-Paris cast was definitely beneficial. In the early stages plenty of intravenous plasma or serum is essential. After the first week ten days the haemoconcentration disappears and secondary anaemia develops. Blood transfusions at this stage help considerably.

Cases of severe burns travel very badly even up to two weeks after burning. After a long journey they arrive toxic and ill; the tongue is dry, and this is a good indication for pushing fluids. The tongue and the pulse are the most helpful guides to the general condition. The colour is often difficult to determine because the face is involved. Where all four limbs are burnt a transfusion may be given into the sternum.

It is easy to put too much sulphanilamide powder on burns, especially in severe cases, as sulphanilamide is read

and quickly absorbed from burnt areas and gives rise to profound toxæmia. I have seen one patient with a blood sulphamylamide of 20 mg. per 100 c.c.m., and another (fatal) dose of 40 mg. entirely due to local absorption (optimum concentration 5 mg. per 100 c.c.m.). These patients were very cyanosed, and showed marked dyspnoea, tachycardia, and restlessness, and later unconsciousness. There were no physical signs in the chest. Lieut.-Col. W. C. Wilson pointed out that alphanilamide was responsible. Sulphanilamide is now kept in the theatre in little gauze bags containing 10 g. each—that is the ration per patient. When, after a long journey, a burnt patient arrives toxic and ill the worst thing to do is to dress him the same evening. Plenty of fluids, and morphine $\frac{1}{4}$, should be given, and the patient must be left alone to recover from the journey. The burns should be dressed before and not after evacuation, and frequent dressings are harmful. Burns of the back are difficult to treat and to move.

Nursing and General Treatment

After heavy fighting the casualties arrive dead tired, and desire nothing but sleep, and lots of it. If they are not overcome with tiredness they want plenty of tea, a good meal, a good wash, and a good sleep. Next morning the bowels need attention. Constipation is very common, perhaps owing to the lack of water in the desert; many patients had not had their bowels open for four days or a week. A No. 9 pill, followed by mag. sulph. in the morning, is the answer. Ill patients are less disturbed if an enema can be given. Many complained of sore backs, from being jolted in an ambulance. Some huge bedsores were seen in patients who were too ill for evacuation and had to be nursed in the forward areas for some days on stretchers without ring pillows. Morphine $\frac{1}{4}$ or mist. 315s (pot. brom. gr. 15, chloral hydrate gr. 15, iact. opii gr. 15) is most useful, and certain cases of battle euphoria respond very well to luminal gr. $\frac{1}{2}$ t.d.s. for two days. Patients do not bother much about their wounds or the loss of a limb; this is in marked contrast to the mental distress caused by an amputation due to an accident. A grenade exploding in the hand causes the most ghastly wounds; several cases have been seen. One or both hands are blown off or mutilated; the face is spattered and the sight of one or both eyes is destroyed. Life continues and the patient recovers, but without hands or sight. For multiple superficial grenade wounds of the limbs a hot soapy bath is excellent treatment if sufficiently sterile conditions are obtainable.

Transfusions.—In all, 328 pints of blood (mostly stored) and 96 pints of plasma or serum were used in the hospital during the last six months of 1942, apart from a considerable quantity of 5% glucose in N/5 saline. Transfusions were used for shock, for burns, and during convalescence when the haemoglobin fell below 60%. For shock two to four pints of blood or plasma were required; the first pint was run in quickly. Patients have been received from forward areas who have had as much as 13 pints of protein-containing fluid during the first day or two. When blood is transfused to anaemic patients with suppurating wounds stored blood has to be given slowly and used with caution, because reactions are common and in the presence of undrained pus the benefit of transfusion is quickly lost.

Gas Gangrene and Tetanus.—Gas gangrene in the true sense has been very rare, and gas infection uncommon. It developed in a badly lacerated forearm with vascular block, in a large undrained haematoma of thigh, and as a terminal event in severe infection of an amputated leg and arm. No case of tetanus has been seen.

Anaesthesia.—Pentothal has been the anaesthetic of choice, especially for short operations. It was used for induction, followed by ether when longer anaesthesia or abdominal relaxation was required. If a drip saline was being given, pentothal was injected into the rubber tubing. Ethyl chloride was also used for induction, especially when the supply of pentothal was running short. Only a very light anaesthesia is required for most cases, and the tired wounded man is easily and quickly anaesthetized.

X Rays.—When the hospital was acting as a C.C.S. a wet x-ray film and report were made available by the radiologist in most cases, and were seen in the anteroom adjoining the

theatre. A radiograph was valuable for showing the presence or absence of fractures and foreign bodies. If the surgeon knows the approximate size and location of a shell fragment he can decide whether to go for it or not. No precise location by x rays was found necessary. The size of the external wound often gave a misleading idea of the size of the missile: a long thin fragment can make a large or small entrance wound, depending on its angle of entry. It was especially helpful to know of the presence of foreign bodies in the knee-joint, skull, spine, and chest. In wounds of the buttock or thorax, where abdominal injury was suspected clinically, a radiograph sometimes settled the matter for or against laparotomy. On one occasion the presence of gas under the diaphragm was a deciding factor.

Deaths

Table III indicates the main causes of death. Probably the figure of 1.3% is approximately accurate for most C.C.S. work. If a patient is fit enough to reach a C.C.S. his chance of

TABLE III.—Mortality in Hospital

	Head and Face	Neck	Chest	Thoraco-abdominal	Abdominal	Shoulder and Scapula	Trunk	Lower limbs	Multiple	Local	Percentage	Died within 1 week of wound	Lived over 1 week
300 casualties from Tobruk, including many serious cases	1	2	1	2			1	1	3				
2,679 casualties from 1st battle of El Alamein and subsequently when acting as a C.C.S.	5	1	2	1	1	3	2	6	9	5	37	1	35
500 casualties from 2nd battle of El Alamein; many seriously ill	8	4	1	3	3	10	3	1	2	12	5	10	35
Total	14	4	4	2	5	11	8	1	2	9	21	11	97

recovery is excellent. The high mortality rate of 3% for the casualties from Tobruk and 10% from the second battle of El Alamein is due to the fact that seriously ill patients were sent to the hospital; this figure is far in excess of the mortality figures in most hospitals.

"Don'ts"

In conclusion, a few "don'ts" may be added:

- Don't suture wounds.
- Don't suture amputation stumps.
- Don't amputate at the site of election; go below it.
- Don't use packing except to stop haemorrhage.
- Don't use drainage tubing.
- Don't use unpadded plasters.
- Don't let a plaster dry with the heel resting on the stretcher.
- Don't forget to give morphine before a long bumpy journey.
- Don't forget to sling a Thomas splint on the stretcher bar.
- Don't forget to give plenty of fluids by mouth.
- Don't forget that the ligature of a main vessel should be prominently recorded on the field medical card and underlined. Gangrene is so dangerous.

Conclusions

The salient features of war surgery in the Middle East have been the value of organized resuscitation and local and general sulphamylamide: the importance of thorough immobilization; the adequacy of conservative surgery and wound trimming (even up to 48 hours after wounding), instead of wound excision; the dangers attendant on tension around wounds and the necessity for a good blood supply in damaged limbs; the satisfactory way in which the wounded man travels (except the abdominal cases and those with severe burns); and, finally, the need to adapt and improvise articles to fulfil functions for which they were never intended. War surgery is not difficult, but careful attention to important details is well repaid by results.

I should like to thank the commanding officer, Colonel G. B. Hadden, for permission to publish this paper, and members of the staff for help and criticism.

ACUTE LYMPHOCYTIC MENINGITIS IN "EPIDEMIC CATARRHAL JAUNDICE"

BY

JOHN WARING, M.B., B.S.

The purpose of this article is to record the occurrence of acute lymphocytic meningitis in a case of epidemic catarrhal jaundice and to criticize the terms "epidemic catarrhal jaundice" and "infective hepatitis." It is suggested that the infectious disease described under these names is not of necessity a condition affecting the liver, but is in fact a general virus infection, such as influenza, in which the primary site of invasion is frequently the gastro-intestinal tract. The advent of hepatitis and meningitis should be regarded as an indication of increased invasive power in subjects whose resistance is low. The conception of influenza should be generic and not specific, so that it may include a number of virus diseases epidemic in nature which at present have not been identified.

The objection to the terms "epidemic catarrhal jaundice" and "infective hepatitis" is that they give a false impression of the disease they represent, because they do not include the diarrhoeal cases, of which there are many, and the simple gastric types, in neither of which jaundice occurs. In support of this view some personal observations are described.

A Gastro-intestinal Epidemic in Letchworth

During the past 15 months there has been prevalent in Letchworth an infectious disease characterized by acute gastro-intestinal disturbance and frequently jaundice, obstructive in type. Three distinct forms have been observed: (1) the diarrhoeal group; (2) the vomiting group; (3) the jaundiced group. These forms have occurred repeatedly in the same household. The diarrhoeal variety has been more commonly seen. The incubation period has been difficult to assess, but may be short or as long as four weeks. There were no symptoms referable to the upper respiratory tract.

The Diarrhoeal Group.—The onset was abrupt, with diarrhoea, colic, and tenesmus, some patients vomiting once or twice during the first few hours. Slight general abdominal soreness was present, but there was usually little constitutional disturbance, and fever was mild or absent. The frequent watery motions continued for 1 to 5 days, then ceased abruptly. In a few cases recovery was delayed and small evacuations of clear mucus were passed in decreasing frequency for 3 to 5 weeks. Only in the acute stage was a fleck of blood to be seen in the motions. In several typical cases cultures from a stool passed within the first 24 hours revealed no pathogenic bacterium.

The Vomiting Group.—In these cases the onset was sudden, with shivering, epigastric discomfort, nausea, and vomiting. At times one or two loose motions were passed on the first day, but subsequently constipation was the rule. There were considerable malaise and prostration, and continuous fever, which rose to 102°, persisted for 4 to 6 days, then fell by crisis. Vomiting continued during the period of fever.

The Jaundiced Group.—The clinical picture was similar to that of the vomiting group, but epigastric discomfort was more severe, amounting to pain. Patients complained bitterly of this symptom. Repugnance to food was usual, being associated with marked nausea and vomiting, which continued until the fourth or fifth day, when jaundice appeared. Thirty-four jaundiced cases have been observed, and in nearly all of them the liver was palpable and tender; sometimes the enlargement was considerable. In only one case was the spleen definitely felt, and this accompanied a much swollen liver. Jaundice may be slight, visible only in the urine or eyes for a day, or deep and fluctuating, persisting for five weeks. The average case was yellow for 6 days. A considerable degree of debility was present after convalescence was established, which delayed return to normal health for 4 to 6 weeks.

A Case of Acute Lymphocytic Meningitis

A man aged 27 developed meningitis *pari passu* with jaundice. His case was made more perplexing by the fact that he is a proven case of pulmonary tuberculosis, in which clinical arrest was achieved one year ago.

On Dec. 20, 1942, he became shivery and complained of headache. Vomiting occurred once or twice each day, and his temperature fluctuated between 99° and 101°. On Dec. 25 the conjunctivae became definitely yellow, but were clear the next day. Headache varied in intensity, but on Dec. 30 its severity became agonizing, with paroxysmal shooting pains between the temples. The patient did not look ill though he was obviously suffering considerably with his head. There was no neck rigidity, a questionable Kernig's sign was present, arm and leg reflexes were sluggish, abdominal reflexes were absent, plantar responses were flexor, there was no papilloedema. The urine gave a green reaction with Benedict's solution. On admission to hospital lumbar puncture revealed a slightly opalescent fluid under increased pressure. Mr. relief from headache was obtained after 30 c.cm. of fluid had been drained away. Examination of the c.s.f. showed a small fib web-cloth. A cell count gave 544 mononuclears (mainly lymphocytes) and 24 polymorphonuclear leucocytes per c.mm. The chloroform content amounted to 710 mg. and protein to 75 mg. per 100 c.c. Sugar was absent, and globulin increased. A scanty centrifuged deposit gave the following results: Gram film—no organisms seen; Ziehl-Neelsen stained clot—no tubercle bacilli seen; cultures on blood, legumin agar and in peptone broth were sterile after 24 hours incubation.

Jan. 1, 1943.—Lumbar puncture performed and 25 c.cm. of colourless fluid under increased pressure allowed to escape. Cell count, 300 per c.mm. Reflexes still sluggish, but abdominal reflexes now present.

Jan. 3.—Vomiting ceased. Temperature normal.

Jan. 5.—Patient looked well, sitting up in bed. Arm and leg reflexes were easily obtained. Lumbar puncture performed and 20 c.cm. of clear fluid under slightly raised pressure drained away. Examination of c.s.f. showed a clear colourless fluid with no cell count. A cell count gave 336 mononuclear cells (mainly lymphocytes) and 56 polymorphonuclear leucocytes per c.mm. The chloroform content was 715 mg. and protein 80 mg. per 100 c.cm. Sugar: Fehling's reduction present. Globulin slightly increased. Convalescence uninterrupted except for intermittent headache of mild degree for three weeks.

An intensive course of sulphathiazole, which was well tolerated, was given by mouth for five days (12, 8, 6, 6, 6 g.) after admission to hospital. Since the cerebrospinal fluid became clear in 48 hours it would seem that the drug was beneficial.

Conclusion

It seems reasonable to deduce from these observations that the current epidemic in Letchworth is a virus infection primarily affecting the gastro-intestinal tract; that the weight of infection more commonly falls on the small and large bowels, producing an acute catarrhal ileocolitis, the degree of gastric involvement being minimal and hepatitis absent. Less often the stomach bears the brunt of the infection and colitis is minimal. The present epidemic the majority of gastric cases develop hepatitis in greater or lesser degrees of severity. Approximately one case of jaundice has been seen for every six cases of diarrhoea—i.e., an incidence of 14%. Uncommonly the virus invades the leptomeninges, causing an acute lymphocytic meningitis reaction.

A number of severe cases of influenza, as distinct from febrile catarrh of the respiratory tract, have occurred recently in which diarrhoea with colic and abdominal discomfort was the initial phase. After 36 to 48 hours invasion of the respiratory tract occurred, starting as a tracheo-bronchitis and later becoming a bronchiolitis with pulmonary congestion. Outbreaks of jaundice in other parts of England have been reported in which the upper respiratory tract seemed to be the primary site of invasion.

The influenzal epidemic has different features each year. It may be gastric or intestinal with vomiting or diarrhoea, gastro-hepatic with vomiting and jaundice, tracheal with cough and substernal soreness, pharyngeal with pain in the throat or simple fever with malaise. Retro-orbital pain and headache are almost constant and often severe, but may be slight or absent in the gastro-intestinal forms. Whichever type invades the community, it seems to breed true to a remarkable degree for about a year. The cases which differ from the current

form frequently start with the usual symptoms, and thus a different variety becomes established imperceptibly.

What benefit is to be derived from describing epidemic catarrhal jaundice as a separate clinical entity? It is stated that outbreaks of the disease often accompany an increased incidence of diarrhoeal disorders and that the initial symptoms may be of the "influenzal" type. Only one form of the disease is described by this name, and therefore it is misleading. These facts surely support the adoption of a wider conception of influenza.

Summary

It is suggested that the application of the term "influenza" be generic; that the names "epidemic catarrhal jaundice" and "infective hepatitis" are unsatisfactory, and that "influenzal jaundice" or "hepatitis" would convey a clearer conception of the disease.

A case of acute lymphocytic meningitis occurring in influenzal jaundice is described.

I wish to thank Dr. P. F. Wilson for his permission to publish this case, and the pathologist, who desires to remain anonymous, for allowing me to include his reports on the cerebrospinal fluid.

PSEUDOSCLERODERMIA

BY

R. B. McILLAN, B.Sc., M.D., M.R.C.P.E.

Physician-Superintendent, Eastern General Hospital, Edinburgh

The following case of pseudoscleroderma arising from multiple deficiency may be of interest owing to the rarity of the condition.

Case History

A man aged 63 was admitted to hospital on July 15, 1941, complaining of stiffness in his legs, which prevented him from walking. He stated that he had been perfectly well until approximately one month before admission, when his right knee-joint suddenly swelled and became painful, forcing him to rest in bed. This swelling was attributed to a slight injury received to the same knee two days earlier which caused only momentary discomfort. After a few days in bed he noted that the skin of both his legs below the knee was becoming darker in colour than usual, the right leg being more involved than the left. This discoloration extended, and within he next seven to ten days it had involved the skin all over his body, being most pronounced on the face and neck, the backs of the hands and the wrists, and the legs from mid-thigh down. During this time he had been rising to attend to his own wants, but about 14 days before admission he began to have difficulty in straightening his legs at the knees. This stiffness progressed, and for some days before admission he was confined to bed with his knees fixed in a position of semiflexion. He stated that he had been feeling tired or an indefinite period, and that for the past month his bowels had been loose. There was no history of sore tongue or of Raynaud's syndrome.

The patient was unemployed, and his total income was 16s. 6d. a week from public funds. His expenditure was 4s. 6d. a week for his bed in a lodging-house, 2s. for tobacco, and the rest for food, etc. He did not drink alcohol. He cooked for himself, and lived mainly on pies, sausages, white bread, and scones, never eating fruit or any vegetables except a very occasional potato, and using condensed milk and margarine in place of fresh milk and butter. There was no previous illness of any note.

Clinical Condition

Routine examination revealed a small, thin, wasted man with a light-sepia-coloured skin with uniformly darker areas on the face and neck, backs of hands, and legs from mid-thigh to mid-dorsum of the foot. There was no special pigmentation around the nipples, in the pubes, or on points where pressure from clothing normally occurs. He was edentulous, had pale mucous membranes, a dry flazed but not inflamed tongue, atrophic ribbed finger-nails, pure white luxuriant hair, and patches of brown pigmentation on his uveal mucosa. There was no circumferential injection or cheilosis. Both corneae appeared healthy, and there were no petechiae or evidences of deeper haemorrhages. He appeared comfortable, but was slightly inattentive and confused. The skin around both his legs from 6 in. to 9 in. above the knee-joints to about the middle of the dorsum of his feet, but not on the soles, was brown in colour, thick, hard, and glossy to touch, was hairless, and could not be moved on the underlying tissues. The skin elsewhere, although discoloured, was of normal consistency and mobility. The thickened skin was raised slightly above the normal skin, and the junction between was sudden (within 1/4 in.) and uneven. The legs were

not swollen and were not tender on pressure. Sensation over the affected area was dulled but not entirely absent. Both legs were held flexed at 45 degrees at the knees, and movement at these joints, which were not swollen, was painless but limited to a range of 45 to 60 degrees flexion by the tightness of the surrounding skin. Movement at the ankle-joints was also slightly limited. Movement at all other joints was normal. Further examination revealed no physical defect, and the remaining points of particular interest which helped in making a diagnosis are:

Skin temperature steady at 97.4°; pulse 75 to 80 a minute, regular; blood pressure 145/80. Test-meal (including histamine): no free HCl. Faeces 4 to 6 soft paste motions daily; total fat 33.9 g.—split fat 27.2%, unsplit fat 72.8%. Urine: routine tests negative; ascorbic acid (estimated as reducing substance), nil; creatin, 14 mg. per 100 c.cm. Blood: W.R. negative; plasma proteins, normal; urea, etc., normal; B.S.R. (Westergren), 6 mm. per hour; plasma ascorbic acid, 0.10 mg. per 100 c.cm.; sugar tolerance, normal curve; R.B.C., 3,310,000 per c.mm.; Hb, 38%; C.I., 0.58; W.B.C., 8,200 per c.mm. Film showed poor filling of red cells, anisocytosis and poikilocytosis, and a normal differential white count. Radiographs of knees showed only slight atrophic arthritis. Cuff test (Hess), negative. Microscopical examination of biopsy from affected skin resulted in the following report:

"The tissue consists mostly of vascular scar tissue. Enveloped in it are small foci of adipose tissue and dense fibrous fascial bands; on one side is striped muscle, which, at margin of scar tissue, is partly atrophied, partly hyperplastic (sarcolemmal cells proliferating). There are recent haemorrhages in the scar and also scattered granules of old blood pigment (previous haemorrhages probably). The appearances suggest scar formation in and adjacent to muscle and perhaps accentuated by haemorrhage."

Diagnosis

On the history and findings recorded above a multiple deficiency state was diagnosed, obvious deficiencies being nicotinic acid, ascorbic acid, and iron. The general pigmentation was considered to be part of the pellagroid change, and the thickened skin on the legs to be the result of this plus very minute multiple haemorrhages, the result of the vitamin C lack. The probability that other deficiencies aided in producing the curious localized change in the legs was great, but it was impossible to estimate their part in doing so. The diagnosis was made, therefore, of pseudoscleroderma the result of vitamin deficiency, and support was lent to this by the earlier records of a precisely similar change occurring in the legs of old people with scurvy (Pfeiffer, 1918). Other causes of the changes that were considered and excluded on the facts which have been given were: (a) true symmetrical diffuse scleroderma (sclerodactylia); (b) chronic cellulitis of legs with, as superadded causes of the general pigmentation, Addison's disease, haemochromatosis, and chronic vermin infestation of the skin. The presence of creatine in the urine was considered normal at the patient's age.

Treatment

Treatment was designed to test this diagnosis, and was conducted in various stages. The first stage was the maintenance of the patient for a period on the ordinary hospital diet, in order that its action could be assessed: the successive stages consisted in the addition to this diet of the obviously absent vitamins, in order that their action in promoting cure could be assessed also. Ascorbic acid was replaced first, mainly because the condition had been described before in association with scurvy.

Table showing Results of Treatment

Clinical Feature	Stage I: 18/7/41 to 18/8/41 Ordinary Hospital Diet	Stage II: 18/8/41 to 8/10/41 Ord. Diet + 7,000 mg. Vit. C in 14 days, then 200 mg. Daily by Mouth	Stage III: 8/10/41 to 24/1/42 Ord. Diet + 200 mg. Vit. C + 400 mg. Nicotinic Acid Daily by Mouth	Stage IV: 24/1/42 to 9/3/42 As Stage II + 1,000 I.U. Vit. B.I.M.I. Daily
Blood R.B.C. Hb	3,970,000 50%	4,150,000 66%	5,000,000 75%	5,000,000 79%
Bowels	Stools still frequent and soft	Improved but not normal	Normal	Normal
Mental state	As on admis- sion	Slight improve- ment	Marked improve- ment to normal	Normal
Pigmentation	" "	Slight improve- ment	Marked im- provement	Normal
Skin thickening	" "	Very slight improvement; smaller area involved	Great im- provement; small slightly thick- ened area on skin only re- mains	Completely healthy skin
		Knee move- ment 35°-60° flexion	Knee move- ments full and free	

The accompanying table shows the details of each stage of treatment, its duration, and the changes in the clinical features of the case as each stage was concluded.

On completion of treatment the initial tests were repeated, and it was found that all those previously abnormal were now normal. Creatine in small amounts was still being excreted in the urine. The patient was discharged well on May 1, 1942, and when last seen (Oct., 1942) was still free from recurrence of the skin lesion.

Comment

The little change shown in the skin, etc., of the legs when only ordinary diet was given, and the marked improvement ending in complete cure when the diet was supplemented and the existing deficiencies were corrected, suggest that the diagnosis of pseudosclerodermia arising from multiple vitamin deficiency was correct. According to the table the most marked improvement occurred when nicotinic acid was given, suggesting that it was lack of this factor which was mostly responsible for the condition. This may be so, but whether nicotinic acid would have had such a marked action in the absence of adequate vitamin C nutrition is doubtful, as in multiple deficiencies vitamins are notoriously interdependent for their action. It is only possible to suggest that the combination of deficiency of nicotinic acid, ascorbic acid, and thiamin, in that order of importance, precipitated the pseudosclerodermia.

The slow response to treatment was not considered abnormal, as this is often a feature in multiple-deficiency states, and particularly so in lesions affecting the skin (O'Leary, 1942). Quicker results could have been obtained had all the missing factors been supplied together. The failure of the lesion to respond to replacement of vitamin C only, plus the failure of the author to observe any condition really closely resembling sclerodermia—although skin thickening was often seen—in 58 old people with clinical scurvy observed over the past five years suggests that the lesion noted in association with scurvy by Pfeiffer, if really resembling sclerodermia as did the case described above, was the result also of multiple deficiency, vitamin C not being the most important lack.

Changes faintly resembling certain stages of true sclerodermia may result from vitamin deficiency and are not uncommonly found. The changes seen and the factors responsible are: (a) subcutaneous oedema, causing apparent skin thickening and fixation and muscle tenderness from lack of vitamin B (Eddy and Dalldorf, 1941); (b) atrophy of epidermis, papillary oedema, papillary capillary dilatation, slight oedema of the dermis, and pigmentation from lack of nicotinic acid (Eddy and Dalldorf, 1941); (c) subcutaneous haemorrhages causing thickened skin and pigmentation due to lack of vitamin C; and (d) atrophy of muscle fibres in experimental animals, due to lack of vitamin E (Pappenheimer, 1939; O'Leary, 1942).

Other records of pseudosclerodermia of nutritional origin are few. Reports of cases which might have had this origin are: (a) a lesion similar to that described in this paper in a patient in association with Sjogren's syndrome (Sheldon, 1939); and (b) a lesion in a poorly nourished woman in whom cure resulted when a good diet was given (Meakins, 1926). It is suggested that it might be more common than is thought, and, as support, attention is drawn to the reports of sclerodermia appearing in patients debilitated by cancer of various organs, in some of whom it disappears when the cancer has been treated and the general nutrition improved, good food being noted to be particularly beneficial in one instance (Behrman and Forman, 1939; Bezecny, 1935).

It is not suggested that vitamin deficiency is the cause of true sclerodermia, and a search has failed to reveal any example of vitamin deficiency or deficiencies causing a change which microscopically resembles the true condition. As the clinical resemblance may be very great the importance of a biopsy in making a diagnosis of sclerodermia is obvious, as without it mistakes could be made and the patient given an entirely wrong prognosis and treatment.

Lastly, although it is not intended to discuss vitamin C in general, the need of this substance by healing wounds (Crandon *et al.*, 1940) is well shown by the behaviour of the biopsy in this case. The wound made on Aug. 3, 1941, when the patient was subscorbutic, showed little healing by Aug. 18, after which date the rate of healing accelerated markedly, the wound being

firmly closed by Aug. 27. This acceleration corresponded to the addition to the patient's diet of 500 mg. of vitamin C daily by mouth, and was obviously governed by it, as all other factors were unchanged.

PNEUMONIA TREATED WITH SULPHAMETHAZINE

REPORT OF 77 CASES

BY

B. A. PETERS, M.D., D.P.H.

Medical Superintendent, Ham Green Hospital, Bristol
AND

M. L. EASBY, M.B., Ch.B.

Assistant Medical Officer, Ham Green Hospital, Bristol

During the latter part of the past winter we have treated 77 cases of pneumonia with sulphamethazine (2-sulpha-4:6-dimethyl pyrimidine), one of the latest additions to the sulphonamide group. It is built up on the same plan as sulphadiazine, with the addition of two methyl groups to the pyrimidine ring. This addition is claimed by the makers (I.C.I.) to increase the solubility of the drug and render its deposition in the kidneys unlikely. This effect was a serious disadvantage of sulphadiazine.

Of the 51 bronchopneumonias treated in the under-12 group 30 were secondary to measles, 2 to whooping-cough, and the rest primary. The ages varied from 4 weeks to 85 years. The normal dosage of sulphamethazine employed, as recommended by the makers, is 8 g. daily for an adult, given six-hourly in 2-g. doses. As children take these drugs better than adults we assumed the adult weight for the standard dose to be 8 st., and gave a fraction of this dose according to their weight—that is, a 4-st. child received half the adult dose and so on. The full dose was given for four days, and half the dose for a further two days. Plenty of fluids were administered, and oxygen tents were used as considered necessary.

We were unfortunately unable to estimate the blood concentration with these doses. All the cases responded more promptly to the drug the earlier in the disease it was given. We think the response in cases responding favourably is slower than with sulphyridine, but the mortality was low, as only three died (4%). One 13-weeks-old baby with whooping-cough and bronchopneumonia was admitted on the sixth day and died four days later. Another fatal case had measles and bronchopneumonia, was admitted on the sixth day of disease, and died on the fifth day after admission. One patient with extensive bronchopneumonia—a female aged 26—survived only 12 hours after admission. Nine other cases showed no obvious response to the drug within six days, but eventually recovered.

Out of 77 patients, therefore, 65 appeared to respond and 12 did not; three of the latter died. Of those not responding, 6 cases in adults appeared to be aberrant cases of lobar pneumonia. From one of the children who did not respond a nearly pure culture of *Staph. aureus* was found in the sputum, and she developed a staphylococcal pyaemia. Not one case in the series developed an empyema.

Toxic Effects

Owing to the risk of renal blockage and urinary suppression with the related sulphadiazine, a careful watch was made on renal secretion. One child aged 2 showed almost complete sudden urinary suppression for one day. On stopping the drug the renal flow was restored within 24 hours. No crystal

were visible in the urine, which showed only a trace of albuminuria. This patient, and two others under 2 who showed no chemical or microscopical abnormalities in the urine or any suppression, developed a curious painless brawny oedema of the whole legs and arms. The tissues did not pit on pressure. The appearance of the extremities was such as is sometimes seen in children with a tendency to chilblains during cold weather. It appeared to be due to some form of circulatory disturbance. It was not due to cold, as the wards were well heated, and the condition passed off in all three cases within 36 hours of stopping the drug. All three children were acutely ill, and were being treated in oxygen tents. They had some cyanosis of the face, due to the primary disease. All three made a good recovery. We had not observed this condition previously in any patients treated with other sulphonamides. In one other case there was a transient haematuria without any crystal deposit and without diminution of urinary flow. The drug was continued in this case without any obvious ill effect.

Apart from these possible toxic effects, sulphamethazine was extremely well taken. Vomiting was entirely absent. Slight nausea in three cases did not necessitate stopping the drug. There was no mental disturbance or depression, which are such a marked feature of cases treated with sulphapyridine. Many of the patients developed good appetites during early convalescence and were able to take large amounts of food without inconvenience while still receiving the drug. The non-toxicity of the drug was especially noticeable with middle-aged and old patients. Cyanosis was not as pronounced as with other sulphonamides. Our conclusions so far are that this is the best drug we have used for pneumonia, especially for older patients.

Working in this hospital, Ormiston, Woodman, and Lewis (1942) had a very similar mortality rate in a similar series of 140 cases treated with sulphapyridine. In another series of 120 cases (Peters, Woodman, and Lewis, 1939) reported from this hospital the mortality rate was 9% with sulphapyridine. In the accompanying table we mean by "response" that the patient became afebrile and began to improve within the period stated.

Age Group	Response to Sulphamethazine in Days								No Response within Six Days	Total
	2 Days		3 Days		4 Days		5 Days			
	Br.	Lobar	Br.	Lobar	Br.	Lobar	Br.	Lobar		
0-2	6	1	4	1	4	-	-	-	5*	21
2-12	6	3	9	4	5	1	1	1	5*	30
12-40	2	3	-	3	-	-	-	2	1*	15
40 and over	1	2	-	2	-	4	-	-	2	11

* 2 died. † Died.

Summary

A series of 77 cases of pneumonia treated with sulphamethazine is reported, with a death rate of just over 4%.

The drug is extremely well tolerated at all ages, and appears to be remarkably free of serious toxic effect, especially in middle-aged and elderly patients. The results are as good as with sulphapyridine.

Full details of the official forms of help available to local authorities in running publicity campaigns for the immunization of children against diphtheria are contained in a special brochure put out by the Ministry of Health, the Ministry of Information, and the Central Council for Health Education. This provides in handy form a complete guide for any local authority wishing to embark on, or intensify, an antidiphtheria campaign. It is pointed out that as the result of the vigorous efforts already made about 4,000,000 children have been immunized. But there are still over 4,000,000 children unprotected. The need for action, both national and local, therefore remains urgent if the aim of immunizing at least three out of every four children between the ages of 1 and 15 is to be achieved.

THE EFFECT OF INJECTIONS OF H 11 ON THE GROWTH OF MOUSE TUMOURS

BY

DENNIS LEYTON WOODHOUSE, Ph.D., M.Sc., A.I.C.

(From the Cancer Research Laboratory, Pathology Department, The Medical School, Edgbaston, Birmingham*)

In view of the account by Gye, Ludford, and Barlow (1943) of their experiments with H 11 on tumour-bearing mice a summary of tests with similar extracts which were carried out in this laboratory in 1941 and recorded briefly in the Annual Report of the British Empire Cancer Campaign, 1942, may be of value, particularly as the two neoplasms for the most part employed were different from those utilized by the above workers.

The first is a spindle-celled sarcoma, which was produced in 1934 by inoculation of dibenzanthracene into the hind leg of a mouse and has since been transplanted through 170 passages with a high percentage of successful grafts and a very small number of spontaneous regressions. Its characteristics and histology have been intensively studied (McDonald and Woodhouse, 1938), and it has been utilized in a number of investigations, including the anti-cancer properties of various chemicals (Annual Reports of British Empire Cancer Campaign, 1941, 1942), tissue-culture experiments (Jacoby, 1940), and inoculation experiments on the chorio-allantoic membrane of the chick embryo (Jacoby, McDonald, and Woodhouse, 1943).

The second type is represented by benzpyrene-induced skin epitheliomas which also have been employed on a considerable scale for testing the possible inhibitory effects of chemical and physiological substances. Spontaneous regression of these tumours is very infrequent, and the animals may survive in good general health for several months after the appearance of papillomas, so that therapeutical injections can be made over a long period. Moreover, this type of growth permits injection experiments to be started before active invasion of the underlying tissues has taken place—i.e., in the pre-malignant phase (see protocols 4 and 5)—and in a way seems more comparable to spontaneous tumours than to a grafted neoplasm after many passages.

A small number of mice inoculated with a strain of Carcinoma 63 were also therapeutically injected. This tumour material was derived from an animal kindly given by Dr. Ludford to my colleague Dr. F. Jacoby, and is presumably identical with the Carcinoma 63 described in the paper by Gye *et al.*

The Injection Material

The examples of H 11 used were: (a) A specimen kindly supplied by Mr. Thompson of the Hosa Laboratories described as of twice the concentration for normal use. (Designated in the protocols as "Hosa.") (b) Three extracts prepared according to the directions of Thompson and his collaborators (1941) from different samples of normal male urine. (Designated in the protocols as "Birmingham, 1, 2, 3.")

Animal Material

The total of tumour-bearing mice in 8 separate experiments was 104—43 with spindle-celled sarcomas (controls included), 19 with skin epitheliomas, and 22 with "Carcinoma 63" (controls included); 20 epithelioma-bearing animals served as controls for the "epithelioma test," some receiving injections of various chemicals and others no injections or saline only. Large and vigorous animals about 5 months old were used for the grafted tumours. The applications of benzpyrene had been begun when the animals were about 10 weeks old. Although the mice were not of a pure strain they were taken from the same stock of "albino-whites."

All the injections were made intraperitoneally and, in the case of the carcinoma-grafted animals, through the flank opposite to the site of the growth.

Results

A survey of the outcome of all the tests clearly indicates that the H 11 preparation has no inhibitory effect on any of

* Carried out for the British Empire Cancer Campaign, Birmingham Branch.

these tumours. The experiments with Carcinoma 63 (12 animals treated) conform exactly to those of Gye and his co-workers, and need not be reported in detail, and only the protocols dealing with the dibenzanthracene sarcomas and benzyrene skin epitheliomas are given below.

It will be noted that, in experiment 2b, 6 animals were injected with H 11 on the same day as the grafts were introduced. In spite of this, four large tumours developed. Also, in experiment 5, minute warts, at probably a precancerous stage, were in no wise inhibited.

The sarcomas from two animals which had received injections daily for 16 days were examined histologically (experiment 3). Some central necrosis, such as is generally found in tumours at this period, was present, but there were many portions of normally staining sarcomatous tissue. Moreover, the tumours were still capable of vigorous growth, as was proved by re-inoculating fragments into three mice, two of which developed typical sarcomas. The microscopical appearance of a skin epithelioma from a mouse after 20 days' therapeutical injections (experiment 6) showed no material difference from sections of benzyrene-induced epitheliomas in control animals.

Protocols of Animal Experiments with H 11

(1) 18 albino mice, average weight 30 g., inoculated with 155th sarcoma graft August 24, 1941. 16 definite tumours palpable August 29. 6 retained as controls. 10 injected twice daily with preparation Birmingham No. 2 until death of animal.

Results.—Controls: 1 tumour regressed by Sept. 29; remainder grew—period 16 to 35 days. Injected: 1 tumour regressed by Sept. 17; remainder grew similarly to controls—period, 8 to 28 days.

(2) 20 mice inoculated with 154th sarcoma-graft August 6, 1941. 2 animals died, August 9 and 10. (a) 6 untreated, for control. (b) 6 injected H 11 ("Hosa" extract diluted with equal volume of water), starting August 6. (c) Ditto starting August 11.

Results.—(a) One graft—no take. One graft regressed by August 20. 4 large tumours developed; animals survived 30 to 40 days. (b) 2 grafts—no take. 4 large tumours after 24 to 68 injections—i.e., 12 to 35 days. (c) One graft—no take. 5 definite tumours after 26 to 80 injections—average duration 28 days.

(3) 12 mice implanted with sarcoma August 12, 1941. 11 successful takes visible August 17. 6 inoculated with H 11 "Hosa" double strength 1 c.cm. daily for 16 days. (One injected animal died after 10 days' treatment.) Killed with 5 controls Sept. 3 and legs with tumours removed. Combined weight of tumour-bearing legs of 5 controls, 15.3 g.; of 5 injected, 19.2 g.

(4) 6 mice with skin papillomas resulting from 5 months' application of benzyrene solution in acetone. Applications suspended for 1 week before injecting with H 11 (Birmingham 1). These tumours were of different sizes and at various stages of "malignancy." Injections of H 11 for average of 43 days. In all cases the tumours grew, in several instances producing large keratinized masses which appeared by inspection to be at "malignant" stage at death of animal. This was confirmed in some cases by microscopical examination.

(5) 7 mice with papillomas selected at varying stages of development from small "wart" to medium-sized growth, 10 by 10 mm. Injected extract Birmingham 2 twice daily. All the tumours enlarged, and in instances in which two or more warts were present these fused into one large mass, 12 by 20 mm. Average injection time, 26 days.

(6) 6 mice with epitheliomas $7\frac{1}{2}$ by 10 mm. Injected 24 days with "Hosa" extract. Final size, 20 by 28 mm.; no instance of reduction in size. This corresponds to rapidity of growth in many series of control animals used in a variety of experiments.

Summary

In 54 mice bearing grafted dibenzanthracene sarcomas, Carcinoma 63, or induced benzyrene skin epitheliomas no inhibitory effect on the tumour growth was found after prolonged injections of the urine preparation H 11 or similar extracts.

Two sarcomas removed from mice after such injections were successfully grafted into other animals, and histological examinations of treated tumours showed no difference from control material.

COMPOSITE ZIEHL-GRAM STAINING METH FOR SPUTUM, PUS, AND EXUDATES

BY

STANLEY MARSHALL, M.D.

Pathologist, Brompton Chest Hospital

The majority of sputa sent to the pathologist for examination are accompanied by a request for tubercle bacilli "organisms," or for "predominant organisms." Culture usually not required, though this may be undertaken by laboratory either for interest only or to confirm the presence or give more detail of the organisms seen by direct examination. These specimens are examined by the Ziehl-Neelsen Gram staining methods. At least two films must be prepared, stained, and examined. The same applies to pus from various sources—e.g., pleural cavity, glands, or kidney—where tubercle bacilli are suspected. Where large numbers of such specimens are examined daily, as in chest hospitals, big general hospitals, and public health "swab and sputum" laboratories, much time is spent in staining and examining the films. Moreover, the preparation of stains and slides occupies a great deal of the time of the technical staff. A single staining method which would show the presence of tubercle bacilli and "other organisms," both Gram-positive and Gram-negative, would be of great value. The more lengthy search for tubercle bacilli could then be made, while at the same time noting the presence of a probable nature of other organisms. Further examination by culture or inoculation would follow as usual when indicated. Such a method, as used at the Brompton Hospital laboratory, is described below.

Technique of Method

Thin evenly spread films are essential, as three different colours are used; poor films—a disadvantage in any method—are useless. For this reason the method is not recommended for beginners, nor in laboratories where only a few specimens of this type are dealt with.

Fix the films by heat in the usual way.

The following stains and reagents are required: (A) Car fuchsin: a 1% solution of basic fuchsin in 5% aqueous ph (as for Ziehl-Neelsen). (B) Picric acid decolorizer: saturated solution of picric acid in ethyl alcohol, 5 parts; acetone, 1 part. Keep in a well-stoppered bottle or a staining trough with fitting cover. (C) Crystal violet: 0.25% aqueous solution. Gram's iodine. (E) Acetone. (F) Auramine green counterstain.

Only one new stain is used. This I have called "auramine green." It consists of a combination of two basic dyes, auramine, an orange-yellow stain, and China green (or malachite green), which in solution gives more of a blue than a green colour. Gurr's reagents are used. The stain is prepared as follows:

Make 1% solutions of auramine and China green in distilled water. Shake occasionally for 24 hours. A deposit will be obtained with the former; this may be filtered off either before or after the combination of the two stains. Alternatively, the supernatant may be pipetted off after standing. Mix in the proportion of 10 parts of auramine to 11 of China green and filter if necessary. Alcohol is not needed for solution. The mixture keeps well for several months with occasional filtering.

Flood films with A and heat to "near boiling" on the slide. Wash off stain with water. Add B. Wash off stain with water. Add C. Wash off stain with water. Add D—1 minute. Wash in water. Add D—1 minute. Wash quickly in water and apply (auramine green counterstain)—15 to 30 seconds. Do not let the stain on too long or overstaining of the background may occur and differentiation of the organisms be rendered less clear. Wash in water, blot, and dry.

The picture is as follows. Tubercle bacilli are stained crimson, with their beading showing as black dots at intervals.

along the bodies of the organisms. This feature is more obvious in older specimens. *Myc. smegmatis* is decolorized and takes up a greyish-green colour, losing some of its Gram-positive character when treated with acetone. Thus urine sediments or pus from the urinary tract are suitable for examination by this staining method. Gram-positive organisms such as pneumococci and staphylococci appear violet-black, as in the usual Gram stain; while Gram-negative organisms such as *N. catarrhalis* and Friedländer's bacillus are grass-green in colour. The background of fibrin, mucus, and debris takes up a light-green tint, while cells vary somewhat according to their type and age. Thus epithelial cells show bluish-green nuclei with a light yellowish-green cytoplasm. Polymorph leucocytes, if not degenerate, show a deeper staining of both nuclei and cytoplasm, the latter being paler. Old degenerate pus cells take up a more uniform pale-green stain with more or less differentiation between nuclei and cytoplasm. Lymphocytes show a deep bluish-green nucleus, while endothelials appear more mottled, with a paler cytoplasm. As in the ordinary Gram stain, old degenerate Gram-positive organisms take up the counterstain and appear Gram-negative.

Incidentally, auramine green counterstain has been found useful in the direct Ziehl-Neelsen technique in place of methylene blue, and also in Gram's method in place of neutral red or safranin, both for pus smears and films from culture. The colour is restful to the eye (as noted by Mackie and McCartney (1942) for malachite green in the former method). In my opinion, however, the cellular appearances are rather clearer when methylene blue is used, and where this feature is of importance the latter stain is recommended.

Medical Memoranda

Blast Perforation of Ear-drums

The following short notes on 60 cases of blast-perforation of the ear-drums occurring simultaneously among Indian troops in the Middle East following a land-mine explosion may be of enough topical interest to merit publication.

HISTORY OF CASES

All these men were within fifteen yards of the mine, and some as near as five yards. Casualties were admitted to hospital within three hours of the explosion, and the ears of all 82 immediate survivors were examined, when 60 were found to have traumatic perforation of one or both tympana. In all, 100 drums were perforated, 50% in the antero-inferior quadrant, the remainder showing either a posterior perforation or a horseshoe perforation involving the greater part of the membrane. Tuning-fork tests revealed a middle-ear deafness in each case, and, although sepoy are not very suitable subjects for such tests, the majority of them showed a diminution of absolute bone conduction also for several days after the accident.

Preliminary treatment in all cases consisted in the insufflation of sulphanilamide powder, followed by packing the ear with sterile gauze. Nine ears were occluded with wax and were left severely alone until three weeks after the injury. Only three of these nine drums showed a perforation at the end of that time. Of the two cases in which syringing was employed to remove wax both became infected, although they dried up subsequently within a fortnight. The proportion of drums infected was 38%, four of which were classed as severe infections, while two of these required a cortical mastoid operation two weeks after the accident. In both these cases the drum and the post-auricular wound were dry and had healed five weeks after operation. All infected cases received sulphyridine, 1 gramme 4-hourly for five days, and many of the cases were put on sulphyridine for their other injuries.

All but four drums were dry within four weeks; but as it was impossible to keep all the patients in hospital until their drums had healed the percentage of complete recovery is not available; 45% were healed within four weeks.

CONCLUSIONS

The antero-inferior quadrant is the commonest site of injury. The proportion of infection to be expected under the most ideal conditions is 35 to 40%.

Insufflation of sulphanilamide powder is probably of value in preventing infection.

Deafness is of the middle-ear type, superimposed upon a permanent nerve-deafness.

The subsequent damage to hearing is not marked.

Captain, I.M.S.

Reviews

LECTURES ON MEDICAL ETHICS

Medical Ethics. By Rupert M. Downes, M.D., M.S., F.R.A.C.S. Based on a course of lectures by Dr. A. V. M. Anderson at Melbourne University. (Pp. 78. 5s.) Melbourne: Published by Ramsay (Surgical) Pty., Ltd., 340, Swanston Street. Obtainable at all booksellers.

This modest volume may certainly be commended to the junior practitioner as he enters on the responsible duties of his profession. It offers information and advice relative to positions which are met but imperfectly in the technical medical curriculum but are none the less important in the doctor's life and conduct as these are related to his colleagues, to his patients, and to the State. The advice in all the circumstances contemplated is excellent in itself and is based throughout on the recognized traditions of the profession. The author's persuasive style gives the book an attractive literary quality. If the subject offers little opportunity for originality in substance the manner in which the teaching is presented is both pleasing and effective.

There is no attempt to cover all the situations included in the department of forensic medicine. Rather the purpose is to explain and justify professional obligations which arise less from rigid rules than from personal opportunities and seemingly customs and courtesies. In this respect the book is both comprehensive and well balanced. If we may suggest an addition it would be a paragraph on the value of personal insurances as a wise protection against the risks and contingencies which are part of the common lot.

The author acknowledges his indebtedness to the well-known textbook of the late Dr. Saundby, but he is mistaken when he suggests that there are not more recent counsellors in the field. Two limitations may be noted. First, not all legislation affecting medical practice in Australia—for example, the compulsory notification of venereal disease—applies in Great Britain; and, secondly, the book wants, and the anxious inquirer desires, an index.

NUTRITION OF MOTHER AND CHILD

War-Time Food for Mother and Child. By Geoffrey H. Bourne, D.Sc. (Pp. 78. 2s. 6d.) London: Oxford University Press, 1943.

In less than 100 pages the author has succeeded in simplifying the nutritional problems that beset expectant and nursing mothers and their offspring. There are chapters which deal lucidly with the difficult periods in a child's life—infancy, kindergarten, and school. The advice given on weaning is excellent and should prove most helpful to the harassed mother. Since the publication of this book official action has been taken to supplement the maternal diet with cod-liver oil and vitamin C. However, there are still women who do not know that capsules of the oil are available, who have difficulty in obtaining them, and who think that liquid paraffin is just as beneficial. A wise dispensation of the Ministry of Food, announced by Lord Woolton, is that from July 25 the expectant mother is to be entitled to two ration books, the additional one enabling her to obtain supplies of food beyond her normal adult ration.

On page 29 the advice about eating cheese seems to be out of its context: there is little iron in this food. The author has rightly stressed the importance of an adequate intake of vitamin C during lactation. He points out that dilution of cow's milk with cereal waters like barley and oatmeal and with limewater is no longer supported by medical opinion. Sugar in excessive quantities for the pre-school child is condemned. It is a pity the "Oslo breakfast" has not been described in more detail. Dr. Bourne asks what has happened to the health sandwiches introduced by those perspicacious medical officers of health, Drs. Milligan, French, and Hunt. These sandwiches were excellent supplements for children, and the author would like them provided throughout the country. We must agree that even in the "best" boarding schools diets are provided which do not contain all the essentials. We would go further, and include hospitals, both voluntary and municipal, in this indictment; and it is a good sign of the times that a

conference on hospital meals has lately been held on the initiative of the Food Education Society. There is no excuse for hospital food being so badly balanced, cooked, and served. It is the old story of good food spoilt in the kitchen. Until the kitchen staff is upgraded in status and pay to that in the operating theatre we cannot hope for improvement.

This book is intended for intelligent parents. It is doubtful whether the mass that throngs our maternity and child welfare clinics will digest some of its contents. But everyone working in these clinics, every health visitor, every midwife, every medical student should possess this nutritional guide.

STONES IN THE KIDNEY

Renal Lithiasis. By Charles C. Higgins, M.D. (Pp. 140; Illustrated. 53.00, post paid.) Springfield and Baltimore: Charles C. Thomas. 1943.

The subject-matter of this book comprises the Beaumont lectures delivered by the author last year. He reminds us that the first x-ray diagnosis of a renal stone was made in 1896 by MacIntyre; Henry Morris first performed nephrolithotomy in 1880, and Beck in 1881 is credited with being the first pyelotomist, but we were under the impression that Czerny of Heidelberg preceded him. From a brief consideration of the history of the occurrence and behaviour of urinary stones the author passes to a discussion of the aetiology, and in this connexion the importance of vitamin A deficiency in giving rise to their formation. The "stone areas" of the world which Dr. Higgins associates with this deficiency are depicted on a map. A poorly balanced diet, particularly on deficient in vitamin A content, was probably the cause of the high incidence of urinary stones in children in the last century both in England and on the Continent. This no doubt explains the fact that accounts of operations on children for stone in the bladder are so often found in pre-Listerian surgical literature. Both renal and vesical calculi have been produced in experimental animals by withholding vitamin A from them, and the author quotes his own and other experimental work bearing on this, and also claims to have produced complete dissolution of calculi by administering a high vitamin-A alkaline-ash diet. On this regime a cystine stone dissolved in 11 months, and after the patient, a young boy, had been free from urinary lithiasis for 6 years, a high-purine vitamin-A-deficient diet produced a small cystine kidney stone in 5½ months. He thus demonstrates the influence of diet in both producing and causing the dissolution of urinary calculi. Other factors in aetiology, such as infections, hyperparathyroidism, gout, etc., are also discussed. Further sections of the book are concerned with the analysis of calculi and their surgical and dietary treatment. Diet tables, a bibliography, and an index complete this valuable little monograph, which should be widely read not only by physicians and surgeons but, we suggest, also by practitioners of preventive medicine, since it would appear that many urinary calculi are preventable.

Notes on Books

Sir ALMROTH WRIGHT has followed Volume I of his series of collected researches, which dealt with *Pathology and Treatment of War Wounds* and was noticed in our issue of Aug. 8, 1942 (p. 159), with Volume II entitled *Researches in Clinical Physiology* (William B. Saunders Medical Books; 12s. 6d.). These miscellaneous papers, which are of wide general interest, are reprinted from various sources, including the *Lancet*, the *British Medical Journal*, the *Journal of Physiology*, and the *British Journal of Dermatology*. The chief subjects treated are the feeding of infants with undiluted citrated cow's milk; the arrest of haemorrhage; the reduction of excessive transudation through the capillaries; coagulability of the blood; and the procedure for dealing with respiratory collapse. The book ends with excerpts from Sir Almroth's *Technique of the Teat and Capillary Glass Tube*. No one should fail to keep the dust-cover on this volume, because the author's preface is to be found there and not in the usual place—between title-page and contents. Like everything he writes, this conversational prefatory letter reflects something of Sir Almroth's personality and is meant to make the reader think for himself.

It is not surprising that a sixth edition and several reprintings of the excellent textbook *A Short Practice of Surgery*, by Messrs. HAMILTON BAILEY and R. J. McNEILL LOVE, have been called for since its first appearance towards the end of 1932. There is little to criticize in this new edition—the best part is undoubtedly the

section on genito-urinary surgery, and perhaps the weakest that the surgery of the nervous system. Although cerebral contusion referred to, its complications and treatment are not mentioned. The commonest intervertebral disk lesion to give rise to sciatica is the lumbo-sacral and not that mentioned on p. 650. Illustrations plentiful and good throughout, but no meningeal haemorrhage have been seen has ever looked quite like that on p. 598 (Fig. 651). The blood clot has always been considerably darker than that shown. The sixth edition will no doubt maintain the well-deserved popularity of this book. It is published by H. K. Lewis at 36s.

A Synopsis of Surgical Anatomy, by Mr. A. LEE MCGRE (John Wright, Bristol; 25s.), has the merit of being written by a practising surgeon who keeps it in line with current practice. The fifth edition is a welcome revision in this respect. The section on intervertebral disk lesions, for example, is an excellent account of modern views. Not all will agree with the author's long (6–10 years) condemnation of Syme's amputation, however, and were disappointed that Lister's tubercle was not referred to in connexion with excision of the wrist or the complications of a Colles' fracture. The recent accounts of the subdeltoid bursa and supraspinatus tendon are good. Throughout the book there are valuable injunctions such as: "In thinking of the shoulder and its lesions, it behoves the practitioner to think of it in terms of joints, the shoulder joint and the subdeltoid bursa." We have the highest praise for this book and can confidently recommend the latest edition.

The small book entitled *First Aid at the Incident*, by E. MACDONALD, M.D., D.P.H., has been written chiefly for instruction, at the instance of the Leicester Civil Defence Committee. It has two novel features: one "The Administrative Code of the Air-raid Incident," this is good; the other, "Material during an Air Raid," a possibility but probably rare. Twenty pages out of 123 seems a large proportion to be given to "Warfare." Transport problems are well dealt with. On alcohol it is stated to be a "stimulant": this is not correct. Terms "closed" and "open" in connexion with fractures are not in their right place. There is an excellent index. The manual is on sale to the public at present, but we are asked to state readers who are interested in the matter may apply to Dr. Macdonald, Civil Defence Headquarters, 24, Halford, Leicester, who would then be able more easily to gauge what to seek authorization for the issue of further copies.

Preparations and Appliances

SELF-INFLATING CUFF FOR ENDOTRACHEAL TUBES

Prof. R. R. MACINTOSH, D.M., writes from the Department of Anaesthetics, University of Oxford:

Leakage around an endotracheal tube is of little importance during the maintenance of anaesthesia with an ether mixture from an Oxford Vaporizer, since the ether concentration can be increased at the source to compensate for this leakage. When, however, the anaesthetist wishes to inflate the patient's lungs to achieve "controlled respiration," as, for example, in thoracic surgery, an air-tight junction between the tube and tracheal wall is essential if the gases in the reservoir bag are

to be transferred to the alveoli. The First Assistant to the Department, Dr. William W. Mushin, has suggested a self-inflating cuff on an endotracheal tube which solves this difficulty. It consists of a thin rubber cuff (finger-stall) about 2 to 3 in. long, cemented at each end to the endotracheal tube which has two or three holes cut in that part of its wall which lies under the cuff. When pressure is applied to the reservoir bag the cuff blows up and forms an air-tight junction between the endotracheal tube and trachea, thus allowing the lungs to be inflated easily. I have used the Mushin cuff-tube in combination with the Oxford Vaporizer for major thoracic surgery and have found it entirely satisfactory.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY AUGUST 21 1943

THE NUTRITION MOVEMENT IN CANADA

A review of the development of the nutrition movement in Canada and an attempt to draw conclusions from Canadian experience may at this moment help us to bring matters into focus. A Canadian Nutrition Council first emerged in the spring of 1938 from the consultations of a special committee that had been formed by the Dominion Council of Health in the preceding year. The committee that had given it birth was constituted as the Council's executive body in association with its scientific advisory committee under the chairmanship of Dr. C. H. Best. A broad programme of investigation was drafted. Few surveys of Canadian diets had so far been carried out, though some investigations into the consumption of milk and other protein foods had been initiated by the Department of Agriculture; and in the course of 1937 an inquiry into food purchases in Alberta and into the dietary conditions of low-income families in Toronto had been undertaken. Four further surveys were therefore completed, under the direction of the Council, in Toronto, Halifax, Quebec, and Edmonton; the results were summarized in the *Canadian Public Health Journal* (May, 1941, 32).

The findings of these surveys indicated to the Council that the nutrients in which the diets of low-income Canadian families were peculiarly deficient were ascorbic acid and other members of the B group, calcium, iron, and vitamin A, in that order. It was tentatively estimated that some 20% of the subjects studied were seriously undernourished on a dietetic assessment, while a further 40% were in a borderline state. It has been further remarked that the average gain in weight by recruits to the Canadian Army during the first month of their service is 7 lb. The cumulative effect of these discoveries and of experience both in our own country and in the United States was sufficient to persuade the Nutrition Council to appoint a special committee in the November of 1941, charged with the task of expressing the ascertained deficiencies in terms of food. The committee's report was approved by the Council, and at the same time the Dominion Department of Pensions and National Health established a Nutrition Services Division under the directorship of Dr. L. B. Pett of the University of Alberta. The function of Nutrition Services has been to carry out recommendations of the Nutrition Council. To this end its staff of five (including three field workers) has been directed to work along the following lines: (a) to visit, inspect, and confer with those maintaining canteens in industrial plants with a view to assessing the nutritional value of the food served and to suggest improvements; (b) to help the public by advice on the choice of food, on suitable purchasing to secure a balanced diet, and on proper methods of preparation; (c) to make expert opinion available for the information bureau of the Department of National War Services.

The broad programme laid down by the Nutrition Council in the December of 1941 placed special emphasis upon the requirements of war workers. Accordingly the staff of Nutrition Services had by July, 1942, inspected about 150 war industries, comprising some 200,000 workers; additional information was assembled from a number of other plants; and a report was published summarizing the can-

teen facilities in 363 plants, which are stated to include well over half the war workers of the Dominion. It may be remarked that the delicate task of factory inspection was carried out under the authority of an Order in Council; but in June of the same year the Nutrition Council had suggested that, to avoid annoyance to industry and labour alike, the primary function of assistance to and inspection of canteens in war industries should rest with qualified representatives of the Federal Office (Nutrition Services), but that local groups were urged to make investigations into industry and the homes of industrial workers a part of any nutrition programme after consultation with Nutrition Services. A series of wholesome suggestions follows, closing with the recommendation that Divisions of Industrial Hygiene in Provincial Departments of Health shall co-operate with Nutrition Services.

The supplementary features of the programme proposed for the guidance of Dr. Pett and his colleagues are of some interest. All pamphlets used for nutritional education were to be reviewed and suggestions made for their simplification and standardization; studies were to be undertaken as to the best method of spreading nutritional information; use was to be made of the schools and the education departments; and, finally, Nutrition Services was envisaged as a central clearing-house of information on nutrition, which might assist in co-ordinating nutritional research in Canada. At the same time it was suggested that various existing groups might well be organized into provincial committees as a basis for the development of future campaigns. It is evident from the published material that the provincial committees, set up during 1942, are viewed as the intermediate link between the central authority in Ottawa and the community nutrition committees, through which the essential work is done. The provincial committees have been formed under the Provincial Departments of Health; and it has been their function to organize the province for the advance of the nutrition programme in all its aspects, as well as to advise the central authority on appropriate methods of education. The community nutrition committees are assumed to spring from the initiative of local interested groups or individuals. In the literature officially distributed such groups are recommended to establish a committee with representation from as many suitable bodies as may be approached. A model structure for local committees is laid down; and it is stressed that *liaison* with the provincial committee shall be maintained. The main work of the local committees is recognized as being education; and it is proposed that, through the activities of volunteer trained home economists, small classes of "leaders" shall be trained from every part of the community. The need for a carefully thought out plan for a prolonged campaign through lectures and study groups is stressed, and an outline course of six lectures on the main dietary defects believed to be common in Canadian homes has been issued by Nutrition Services. The mention of the use of posters, of well-advertised public meetings, of the radio, and of the co-operation that might be invited from restaurants and retail stores suggests that the promoters of the movement contemplate a popular campaign of some size.

It will be instructive to observe, as news comes through, how this campaign succeeds. The results of inquiry into factory canteens and cafeteria will be of import to every country that has to deal with the problems of war industry. Similar surveys in our own country, where detailed figures are still inaccessible to the general public, would also bring out useful information. We already have here a fair number of housewives' groups organized by the Women's Voluntary Services, and a few of them have taken up the study of elementary dietetics. But these occasional efforts

appear to be subject to chance interest or local eccentricity. These "patrolling activities" will be largely wasted unless they are followed up by a mass attack on the whole problem.

MEASUREMENT OF CLOT RETRACTION

Most blood clots contract on ageing, the phenomenon being known as syneresis or clot retraction. It has long been recognized that retraction may be defective in disease, and in recent years haematologists have sought methods for its quantitative measurement. Normally retraction begins as soon as the blood has clotted completely, and proceeds rapidly to a maximum. We may therefore measure either the rate or the extent of retraction of the clot. The latter is the procedure usually employed, the extent of retraction being determined by the amount of serum expressed. The conditions of observation must be rigidly standardized, in particular the calibre of the tubes, for extrinsic factors influence both the speed of coagulation and the amount of retraction.¹ In this country the technique of Macfarlane² is commonly followed, which makes use of a graduated centrifuge tube into which is fitted a cork bored to receive a glass rod. To perform the test, 5 c.cm. of blood obtained by venepuncture is immediately introduced into the tube, the glass rod and cork are fitted, and the tube is placed in a water bath at 37° C. One hour after a firm clot has formed the tube is taken from the bath and the clot is carefully freed and removed on the glass rod. The volume of serum is measured directly, and the result is expressed as a percentage of the original volume of blood. Macfarlane found that the normal serum volume fluctuated between 43.9% and 65.5%; he made no correction for anaemia. Since the entire bulk of the clot is proportional to the formed elements of the blood, some correction for anaemia or polycythaemia seems desirable. The simplest way of doing this is to compare the amount of serum extruded with the plasma-corpuscle ratio of the unclotted blood as determined by the haematocrit. We may call this the serum-plasma (S/P) ratio. Using this index of clot retraction, Van Allen³ found a normal serum output in rabbits of 87% to 100%. A more difficult and less meaningful way of recording the results has been suggested by Aggeler, Lucia, and Hamlin.⁴ They subtract the volume of the corpuscles from the volume of the clot and obtain a figure for the extracorporeal volume of the clot. The mean value for this figure in man was 9.1%. However the results are recorded, it is generally agreed that clot retraction is characteristically decreased in thrombocytopenia and hypoprothrombinaemia, and it may indeed be used as a measure of the latter defect. The test is in no way specific, and low values are also obtained in pneumonia, malignant disease, and occasionally in health.

It is interesting to put up two clot-retraction tubes and observe the second at 24 hours. In health little change will have occurred, but in other cases a greater or less number of red cells will have freed themselves from the clot. Van Allen³ was of the opinion that the quantity of corpuscles which escaped from the clot was directly proportional to the rate of retraction, and could indeed be used to estimate that rate. It would seem probable, however, that both the extent and the rate of retraction are in inverse proportion to the tendency to bleed, and Van Allen's anomalous results are probably to be explained by the fact that he exposed his clots to a good deal of mechanical strain. Certainly most workers with the

Macfarlane technique would agree with Reimann,⁵ who suggests that any considerable extrusion of corpuscles from the clot is an indication of a haemorrhagic tendency. Reimann speaks of this as the "escape phenomenon," and suggests that it indicates an undue readiness of the clot to break down *in vivo*. Nevertheless the sequence of events may be more complex than this. In some cases it may be found that the clot has completely dissolved again at the end of 24 hours. This is the phenomenon of fibrinolysis, which is prone to occur after trauma or operations and which is the basis of the employment of corpse blood for transfusions.⁶ Fibrinolysis may be regarded as the next step after the coagulation of the blood, just as autolysis follows rigor in muscles, though not all would agree with this simile. In any event, fibrinolysis is not evidence of a haemorrhagic tendency but rather the reverse. Taylor and co-workers⁷ have shown that when plasma is clotted by the addition of chloroform fibrinolysis invariably follows, and this fibrinolysis is slower in haemophilia than in health. The "escape phenomenon" may therefore be due either to friability of the clot, which indicates a haemorrhagic tendency, or to fibrinolysis, which does not. To study clot retraction completely, therefore, we should need to measure at least four things: the plasma-corpuscle ratio in the haematocrit; the volume of serum expressed at the end of 1 hour; the output of corpuscles at the end of 24 hours; and the rate of fibrinolysis as determined on the citrated plasma. None of these tests is particularly time-consuming, but it is doubtful whether the energies of the ordinary laboratory would really be well spent on measurements whose clinical and physiological bases are so obscure. In the present state of knowledge it seems wiser to regard the study of clot retraction as a research and not a routine procedure.

ORIGIN OF CHORIONIC GONADOTROPHIN

The evidence that the gonadotrophin excreted in the urine during human pregnancy is produced in the placenta has in the past been largely indirect, since the substance is only transiently excreted in pregnant monkeys and not at all in the lower experimental animals. The theory is based on the appearance of the gonadotrophin in the urine soon after the implantation of the egg and its abrupt disappearance after parturition. Contributory evidence has been supplied by studies of the amount of gonadotrophin that may be extracted from the placenta at different stages of pregnancy. One such study has been made by Bickenbach,⁸ who found that the largest amount present in the placenta two to three months after the onset of pregnancy, when the concentrations in blood and urine were also maximal, was equal to 100 mouse units per gramme of placenta.

Recently, however, definite evidence that the gonadotrophin is actually formed in the placenta has come from America, where Seegar Jones, Gey, and Gey⁹ have reported the formation of chorionic gonadotrophin in placental cells grown in tissue culture. Tissues cultured included 5 placentae obtained at hysterectomy in women 4 to 5 months pregnant, 2 placentae from ectopic pregnancies, 2 full-term placentae, and 2 hydatidiform moles. The supernatant fluid from the cultures was injected into 21-day-old rats, and histological changes produced in their ovaries were studied. Positive results were obtained in 20 out of 28 samples of supernatant fluid: follicle growth in 6 cases and the formation of corpora lutea in 14. There

were positive responses in all the types of tissue cultured, and it is noteworthy that the assays were carried out when the cultures were at least 2 weeks old, by which time there had been several changes in the fluid medium and the culture consisted of several generations of new cells. The cells of all the cultures tended in time to be of a uniform type, identified as that of Langhans's layer of the chorionic villus. Gonadotrophin was demonstrated in the supernatant fluid from one ectopic chorion that had been cultured for six months, though the production of gonadotrophin generally declined throughout the culture period. The authors were not able to show that any oestrogen or progesterone was produced. Their results, however, clearly prove that the gonadotrophin in pregnancy urine is of placental origin, and amply justify its international designation as chorionic gonadotrophin (or -trophin). Incidentally the authors use the term "cyonin," which was coined by Astwood and Greep¹⁰ and is gaining some currency in the U.S.A., though it has at present no international status.

DIMORPHIC ANAEMIA

The two best-recognized nutritional anaemias are the microcytic iron-deficiency anaemia of temperate climates and the nutritional macrocytic anaemia of tropical and subtropical zones. A fact which tends to be forgotten is that iron deficiency may complicate nutritional macrocytic anaemia, the resulting blood picture being confused and at first sight puzzling. Such cases have been observed in both India and Macedonia, and a recent report by Trowell¹¹ describes a large series of cases of anaemia among the natives of Uganda, many of which were found to have the characteristics of a "dimorphic anaemia." In the Tropics there is a tendency to regard anaemia as secondary to some tropical disease until it is proved otherwise. But, as Trowell points out, with modern methods of diagnosis nearly every inhabitant of the Tropics may be found to harbour an occasional malarial parasite in the blood or a hookworm in the bowel. It therefore becomes a matter of some difficulty to decide what constitutes a severe enough infection to be the prime cause of anaemia. In approaching the problem of diagnosis he considers that the first decision should be whether there is any nutritional deficiency present, then whether any disease such as hookworm or malaria is causing or accentuating the deficiency, and, lastly, what other serious conditions are present which might affect erythropoiesis. Trowell analyses his cases on these lines, and further classifies them on the basis of the values for the mean cell volume and mean corpuscular haemoglobin concentration. The colour index and mean diameter are not so useful in diagnosis, as they are frequently within normal limits in the cases of dual deficiency.

Between the two extremes of pure nutritional macrocytic anaemia and pure iron deficiency a high proportion of the Uganda cases fall into the groups "macrocytic hypochromic" and "normocytic hypochromic" anaemias. The former are all undoubted cases of dimorphic anaemia, but the latter may include a few cases of pure iron deficiency. In a typical case of dual deficiency the appearance of the blood smear is quite characteristic. Small hypochromic cells are found in the centre of the slide, forming a striking contrast with the large well-stained cells which collect at the edges and tail. Examination of the marrow shows that there is a mixed megaloblastic, normoblastic, and hypochromic type of erythropoiesis, the proportions varying according to the predominant deficiency. A therapeutic test is a simple additional diagnostic measure, a double

reticulocyte response being obtained with treatment first with iron and later with a crude liver extract. Purified liver extracts are best avoided, as the response is uncertain in nutritional macrocytic anaemia. It is naturally important that any complicating disease should be treated concurrently.

Under wartime conditions it may well be that similar cases of "dimorphic anaemia" may be encountered in Western Europe; the facts assembled by Trowell are therefore of considerable interest.

THE GENUS SHIGELLA

Bacillary dysentery in man is characterized by an acute inflammation of the large intestine, and cases may be epidemic, endemic, or sporadic. Ervin Neter¹ in a review of the genus *Shigella*, the most important members of which cause bacillary dysentery, points out some of the gaps in our knowledge of this group of microbes. Diagnosis is made by successful isolation of the specific organisms from the stool; particles containing pus and blood are the most likely to give positive results. When immediate examination is impossible, the infective material can best be preserved in 30% glycerin in physiological saline tinted with neutral red. More recently good results have been obtained by preserving in a buffered saline solution (pH 8.5) containing 1% sodium citrate and 0.5% sodium desoxycholate. The successful isolation of dysentery bacilli by direct plating on desoxycholate agar is one of the greatest improvements in bacteriology in the last year or two. The Widal test applied to bacillary dysentery presents much difficulty compared with its application in the enteric fevers, and, if employed, a standardized procedure should be carefully followed with proper positive and negative controls. Therapeutic sera and bacteriophage have both been employed in the treatment of dysentery infections, but recent experience with the sulphonamide drugs indicates some of them to be particularly bacteriostatic to the dysentery bacilli. Sulphathiazole and sulphaguanidine have proved most efficacious, not only by inhibiting members of the genus *Shigella* but also because they are fairly soluble in water and are absorbed but slightly from the intestine. Active immunization against the disease would be of value, particularly in wartime; the formaldehyde-treated exotoxin (toxoid) of Shiga's bacillus may be worth a trial.

Several of the species of dysentery bacteria are known under a variety of names, a fact which often leads to confusion. The following members of the genus *Shigella* are recognized as pathogenic to man: *S. dysenteriae* (Shiga bacillus), *S. schmitzii* (Schmitz bacillus), *S. sp.* (Newcastle type), *S. paradyenteriae* (Flexner bacillus), and *S. sonnei* (Sonne bacillus). There is increasing evidence that *S. alkalescens* is pathogenic to man. A primary subdivision of *Shigella* is best obtained by classifying its members according to their action on lactose and mannitol. Group I consists of lactose-negative, mannitol-negative types, including the type species of the genus, *S. dysenteriae*. The only other pathogenic member of this group is *S. schmitzii*. The former organism is indole-negative, forms an antitoxin, and is antigenically distinguishable, in these ways differing from the latter. *S. paradyenteriae* is the chief member of the second group—lactose-negative, mannitol-positive types. This genus is characterized by its members undergoing bacterial dissociation, and each species having several antigenic types; *S. paradyenteriae* (Flexner bacillus) is the chief offender in this respect. Boyd has added considerably to our knowledge of the antigenic

¹⁰ Science, 1939, 89, 81.

¹¹ Trans. roy. Soc. trop. Med. Hyg., 1942, 36, 151.

¹ Bact. Rev., 1942, 6, 1.

make-up of this group by the demonstration of a group-specific antigen. The old biochemical subdivision of Flexner types on the fermentation of maltose and sucrose should be abandoned, as it bears no relation to antigenic types. *S. alkalescens*, another member of this group, is distinguished by fermenting dulcitol and xylose and producing an extremely alkaline reaction in litmus milk. The fact that certain members of the genus are late lactose fermenters was apparent long ago, but it was not until 1915 that Sonne proved conclusively that such an organism could produce clinical dysentery in man. Late fermentation of lactose is due not to a slow utilization of the carbohydrate but to the appearance of lactose-fermenting daughter colonies.

The rapid differentiation of Flexner from Sonne often presents difficulties, as the fermentation of lactose by the latter may require several days or weeks. Usually, however, colonies of Sonne, appearing first as yellow on solid media, soon turn pink to red after 24 to 48 hours' incubation; the smooth Sonne colony is said to be more convex than the Flexner colony. Both soon undergo dissociation to rough forms. The fermentation of rhamnose is said to aid in their differentiation; Sonne's bacillus produces acid in 24 to 48 hours, whereas strains of Flexner fail to do so, or do so only after prolonged incubation. The differential diagnosis of Sonne from Flexner infections by agglutination tests may be difficult owing to an antigenic relation between the two organisms, particularly if rough forms are encountered. *B. dispar*, first described by Andrewes, is identical with *S. ceylonensis* and *S. madampensis* of Castellani. These organisms are included with *S. sonnei* and are differentiated by being indole-positive. There is no conclusive evidence as yet to indicate that these organisms cause dysentery. These strains could be included in a single species—e.g., *S. castellanii*.

Many species of the genus have been studied comprehensively, but knowledge of the other species is lacking, and competent investigators should collect and study strains of these little-known varieties and identify the accuracy of the strains, reconsider their taxonomic position, and determine their pathogenic significance. Again, with the exception of Shiga's bacillus, little is known as to why one species may cause epidemic outbreaks of dysentery whilst a very closely related species does not. Further investigations are required on this basis as well as chemical analysis of their antigenic components.

AN APPEAL FOR BACK NUMBERS

Members who do not preserve the *Journal* for binding are invited to send their copies (preferably in bulk) to B.M.A. House, Tavistock Square, W.C.1, addressed to the Secretary of the Journal Board. The cost of carriage will be repaid.

There is a constant demand for back numbers, and each goes quickly out of print; hence any spare copies published during the war will be welcome. The steady growth in membership to a figure well above 43,000 has increased the circulation of the *Journal* by 12% in the past four years, because every new member must have his weekly copy. Meanwhile there has been a very severe and progressive cut in the amount of paper allowed to be used for printing. Every means of economizing space has been adopted in order to make the paper ration go as far as possible, and nothing more can be done except to reduce the number of pages still further. A member who returns his copies at any time after reading them will in that way put them back into circulation through the Head Office. If the response to this appeal is widespread the help thus given will be very material at a time of great and increasing difficulty.

CHILDREN IN BONDAGE

The Save the Children Fund, founded in England after the 1914-18 war, to bring relief to the suffering children of Europe, made a most important contribution to European recovery. Its founder, Eglantyne Jebb, received less recognition than was her due for her self-sacrificing devotion to child welfare. The subsequent creation of the Save the Children Union linked together the national child welfare associations of 27 States and did much to stimulate increased activity in this vitally important branch of public health and endeavour in many of its constituent countries. The Save the Children Fund has set up a committee to study the problems of post-war reconstruction in Europe in its own special domain. The report *Children in Bondage: Child Life in Occupied Countries*¹ has been prepared for the use of that committee. It contains such information as was available up to June, 1942, regarding conditions of child life in the occupied countries of Europe with the exception of the occupied portions of Soviet Russia, and in Finland. It further provides some information regarding economic and health conditions generally in these countries. All this information is of necessity fragmentary and disjointed. Such vital statistics as the report contains are for the most part bereft of significance by the absence of other essential data. Moreover, conditions are constantly changing, and in the main, unfortunately, for the worse. In spite of this the small volume is a useful reminder of the extent to which the continuation of the war is sapping the vitality of the rising generation and of the nature of the formidable problems that await us in this vitally important aspect of post-war reconstruction. The most informing chapter of the report is that devoted to Finland, which contains information collected by Dr. Herceod during a visit to that country early in 1942. In the chapter on Greece the national child welfare organization, whose work receives appreciative recognition, is called the Patriotic Institute; the Patriotic League is its usual appellation.

THE R.S.M. IN WARTIME

At the recent annual meeting of the Royal Society of Medicine it was announced that the membership of the Society is now just over 6,000, the highest level it has ever attained, and marking a 50% increase within the last fifteen years. No. 1, Wimpole Street is nowadays a very active centre. The meetings of the Society during the past year have been larger in number and better attended than ever, and the Barnes Hall has often been crowded out. In the annual report 55 set discussions which have taken place in the various Sections are listed. Many of these, which have been briefly reported in these columns, have had a close practical application to medical service in wartime, both in the military and in the civil field. The Society has given hospitality to members of the medical services of the British, Dominion, and Allied Forces, and many of the discussions have been enriched by contributions especially from United States and Canadian colleagues. Two distinguished medical men of the United States, Dr. Thomas Parran and Dr. Hugh Young, as well as Prof. A. T. A. Jurasz of Poland, have been elected honorary Fellows. Inter-Allied conferences on military medicine have also been arranged for the benefit of the fighting Forces, the discussions taking place in private. Committees of the Society are now dealing with the subject of interned medical aliens, with education in otorhino-laryngology, and, in collaboration with the Royal Medico-Psychological Association, with the future of psychiatry in all its branches.

POSSIBILITIES OF RESEARCH IN SENILE DISEASES*

BY

S. CIEMAN, M.R.C.S., L.R.C.P.

Medical Superintendent, Southend Municipal Hospital, Rochford

The scope and opportunities for systematic study of and research into diseases affecting the aged are limitless. According to the Life Insurance Underwriters' Association, it is estimated that in 1945, 1 in 8 of the anticipated population of the British Isles will be over the age of 60. Since unemployed elderly men are dependent upon State aid, it is of interest to the State to encourage investigation of diseases peculiar to age and to extend preventive medicine to this field. At present the attitude of both the public and the profession towards the aged and their ailments is negative. Arteriosclerosis, arterial hypertension, cardio-respiratory disorders, nephritis, cancer, diabetes, and arthritis continue to rise. There are books, journals, societies, and University chairs devoted to other special branches of medicine, but, apart from small organizations interested in particular homes for the aged, there is no general or professional body concerned with disease affecting the aged. Special courses or at least lectures should be included in the curricula of medical schools. Clinics should be established, where necessary with adequate laboratory facilities, if knowledge of the normal retrogressive alterations in the anatomy and physiology of the aged is to be developed. In America a research unit has been established under the Federal Health Department to study human clinical problems of ageing and of diseases characteristically associated with advancing years and which involve the mental as well as the physical changes of senescence.

Heredity is probably the capital factor in longevity and the maintenance of a healthy old age. In order to assess heredity as a causative factor in premature degenerative changes, periodic examinations are necessary, since they lead to the discovery of disease tendencies and correction of errors in the mode of living. If a patient's father died of nephritis or his mother of cerebral haemorrhage in the early sixties, a regimen tending to prevent arterial hypertension should be advised. If there is a positive family history of diabetes (and there is believed to be a hereditary factor in 25% of cases) an ageing patient should have "urinalysis" done every three months and blood-sugar estimates or glucose-tolerance curves twice yearly. Heredity is probably the most important aetiological factor in coronary artery disease, the greatest number of deaths from which occur between the ages of 62 and 74. The same applies to hypertension and obesity.

The Actuarial Society of America has shown that at the age of 55, 20% overweight means 25% higher mortality. As obesity in old age is often associated with diabetes, degenerative cardiac, arterial, and articular diseases, and gall-bladder pathology, it is important to pursue investigations into causative factors. The basal metabolic rate is often lowered in obese persons; but this does not signify thyroid deficiency, and thyroid medication is unlikely to succeed in weight reduction. It is now believed that the hypothalamus contains a fat-regulating centre and that there is abnormal irritation of this centre, where feelings of hunger originate an increase of appetite in the absence of exercise, occupational activity, etc.

Study of Subjective Symptoms

There is an immense field for the modification of the clinical descriptions of the various diseases and syndromes as they affect persons of age. In the pre-disease period there are no specific symptoms except a feeling of ill-health, uneasiness, apathy, unexplainable fatigue, and loss of appetite. These subjective symptoms call for a study of the organism as a whole, a complete inventory of the body systems and nutrition, and a synthesis of the data so obtained. Thorough practical laboratory investigations of such elderly people will eventually succeed in detecting the onset of senile diseases, prolonging the duration of

their usefulness to the community, and maintaining their will to live and their self-respect.

Rollston aptly stated that in old age the organs suffer in silence. In the aged, pain is not a safe clue. Owing to diminished nerve sensibility and excitability there may be appendicitis, peritonitis, or strangulated hernia without much pain. Pneumonia may exist with little pain in the chest and little if any rise of temperature or pulse rate. Such patients may be just drowsy, apathetic and prostrate, or restless. Chills are rare at the onset of such acute infections as influenza, pneumonia, or pyelonephritis. The onset of diabetes may be insidious and almost invariably without typical symptomatology. Mild forms with intermittent glycosuria and hyperglycaemia may be of several years' standing, with the patient feeling well, and yet may suddenly become acute, requiring rigid diet and insulin. Hence the importance of glucose-tolerance tests in the aged person with glycosuria, so instituting earlier control, but using a higher blood-sugar figure as the normal physiological basic level.

Investigation into Various Complex Conditions

If the complex conditions which determine arteriosclerosis and its sequelae, cerebral haemorrhage and thrombosis, coronary artery and renal disease, and peripheral gangrene were investigated more thoroughly, it would lead to the discovery of the main causative factors of senility and premature senility with their attendant incapacity. We are aware of the roles of heredity, infectious illnesses, disorders of metabolism, nutritional imbalance, mode of living, etc., but the actual mechanism remains a mystery. To diagnose arteriosclerosis at an early stage remains difficult. Palpation of vessels, examination of ocular fundi, x-ray examinations of chest and extremities, and blood-pressure estimations are not enlightening enough.

It would seem that the approach by thorough blood cholesterol studies is the most helpful at the moment. By feeding cholesterol to rabbits, atheromatous changes in the heart valves and in the intima of the great vessels have been produced. At the age of 45 it may be permissible to try a low-cholesterol diet and desiccated thyroid if hypercholesterolaemia is present, supplemented by the usual measures of correction of overweight, adequate rest periods, avoidance of fatigue, undue excitement, and strain.

Arterial changes are associated with an increase of cholesterol esters in the blood. The possibility of controlling the blood cholesterol through diet is being acted upon. Hypercholesterolaemia is constant in myxoedema. The cholesterol-cholesterol-ester ratio is abnormal in diabetes and obesity, and if the B.M.R. is normal in these conditions and the blood cholesterol high, marked improvement occurs when small doses of desiccated thyroid and a low-cholesterol diet are given.

Occasionally very low blood-pressure values are found in apparently healthy old people. Blood-pressure readings should be taken and charted as are T.P.R., as they vary after a meal, from day to day, from month to month, and from year to year. It is not unusual to find patients who have had an increase in blood pressure over a period of years, and whose blood pressure has become normal again without treatment when they reach the ages of 70 and 75. However, as a prophylactic measure, the cardiac and renal functions should be assessed in every hypertensive. Some observers regard endocrine imbalance as a cause of hypertension, but there is no definite evidence to justify this belief. Goldblatt's experiments in the production of hypertension by clamping the renal vessels and of renal failure by occluding the renal artery promise to shed light on the aetiology of hypertension and its relation to nephritis. Many attempts to detect a pressor substance in the blood plasma which could reproduce the vasopressor state in either animals or men are being made.

Diagnostic Tests

It is necessary to estimate quantitative degrees of renal impairment in treating almost any organic disease in old age, including cancerous conditions of the alimentary tract, pelvic tumour, and arteriosclerotic gangrene requiring surgical intervention. While there is a choice of laboratory investigations for this purpose, no single one of them by itself is reliable, and

* Read to the London and Home Counties Branch of the Medical Superintendents' Society, Feb. 13, 1943.

there is still scope for a renal function test to enable a surgeon to decide on the proper pre-operative preparation and the type of operation. In old age leucocytes and casts are frequently present in urine, often in large numbers, without in any way being pathological.

Various tests for hepatic function are being used, but hitherto none have commanded the confidence of the clinician. Yet it is important from the point of view of pre-operative measures and scope of operation to have a quantitative estimate of the degree of liver damage associated with gall-bladder disease or obstructive jaundice. In such cases, cholesterol esters may disappear from the blood and reduction of hippuric acid will show the degree of damage to hepatic cells.

A clinical diagnosis of chronic myocarditis or myofibrosis should not be made. These labels do not present a picture which can be proved clinically or radiologically. It is only when coronary disease or angina of effort is present, and confirmed by electrocardiographic examination, that it is possible to make a diagnosis which can be substantiated. Heart disease in old age in the absence of valvular disease and renal defect is generally arteriosclerosis of coronary arteries. Since it is difficult to diagnose myocarditis one has to depend upon a study of the function of the heart by its reaction to ordinary physical activity. It is rather discouraging to find that when an elderly patient dies from cardiac defeat after operation necropsy may fail to show any change which would logically account for the condition.

Gastric Disturbances

Absence of gastric acidity increases with age. In a series of 110 elderly people there was absence of free HCl in 66 who were apparently in good health; 76 of the 110 showed signs of atrophic gastritis, demonstrated gastroscopically with diminution or absence of free HCl; but only 14 of these had mild discomfort, while the remainder had good appetites and tolerated their food well. The Hb in this series was frequently diminished, and 24 had red cell counts between 2,900,000 and 3,800,000 per mm. Hence hypochlorhydria is common in old age, and is probably dependent on a symptomless atrophic gastritis. Similarly the proteolytic, lipolytic, and amylolytic enzymes are normally diminished in persons of advanced years. Peptic ulcer is common between the ages of 55 and 79, cancer of stomach between 50 and 79. Gastroscopy and x-ray examination following an opaque meal are the most accurate aids to diagnosis. Many persons manifest the first evidence of peptic ulcer after the age of 60.

Achlorhydria increases in incidence as the years advance, and may precede definite anaemia or cancer by several years. It is not uncommon to discover the first symptoms of pernicious anaemia at 75 or 80 years of age. Every patient complaining of a "weak heart" or symptoms pointing to disturbance of the nervous system must be investigated with pernicious anaemia in mind, although diabetes, myxoedema, or nephritis may be present also, double pathology being quite common in senescence.

It is commonly stated that pernicious anaemia is rare in old age. The majority of cases now seen are in the age period 40-79. If blood counts were done as a routine many more cases would be discovered. Physicians have neglected to look for pernicious anaemia in the aged because they have been taught that it is a disease of middle life.

Defective Nutrition

We have all seen persons who are unable to make the effort to venture out in inclement weather to obtain their rations, with the result that they are admitted to hospital in a cold, wasted, asthenic, and neglected condition or perhaps in coma with an intercurrent infection, feeble and shallow respiration, and a pellagra-like dermatosis. The response to the giving of a balanced diet and parenteral vitamins is dramatic. The debilitated and depressed condition of many persons of advanced age and their vulnerability to infection may be traced to defective nutrition if a review is made of their daily intake, especially in respect of vitamins, minerals, and caloric value. The aged, often faddy in their likes and dislikes, are unlikely to have the necessary variety in their meals, because this entails

partaking of certain foods to which they have never been accustomed. The condition, too, may be aggravated by defective absorption from the alimentary tract and by defective utilization.

Thrombophlebitis is a fairly common condition in the aged—especially in those who are confined to bed for any reason, in the obese, and after operation. It has been shown that the interruption of vasoconstrictor impulses with procaine by infiltration of sympathetic ganglia brings about a normal interchange of intravascular and perivascular fluids. There follows rapid relief of pain and oedema, and fever soon disappears. As with coronary artery and cerebral thrombosis, heparin may be used prophylactically, but the prohibitive cost prevents its general use. Vitamin K has not proved efficacious in the thrombotic conditions of the aged.

Future Possibilities

The future may hold the possibility of using endocrine therapy for prostatic enlargement. Periodic medical examinations with routine attention to the prostate gland will reveal many incipient hypertrophies. Oestrogens, androgens, and gonadotrophins have been tried, but results are not convincing. Much work remains to be done before the possible relationship of the endocrines to prostatic hypertrophy can be visualized. In the meantime, earlier detection of prostatism favours transurethral resections, the mortality rate of which at the Mayo Clinic is 1%, while delay and neglect mean prostatectomy, the risk depending upon the state of the cardio-renal-vascular system and the lungs, and the presence of infection.

Space does not permit me to refer to the preventive measures or the investigations which might be pursued with advantage in elderly patients with incipient impairment of hearing and vision. There is an immense scope for research into the cause and prevention of progressive degeneration of the lungs and the cardio-respiratory complex. Much is to be gained by focusing attention upon the appropriate housing and hospital conditions required by the aged to minimize accidents and to maintain optimum health and usefulness.

Nova et Vetera

THE VIENNA SCHOOL

To medical students at the beginning of this century study abroad was alluring; one envied those lucky enough to be able—not always with solid reasons—to record in the *Medical Directory* the names of foreign universities in which they had continued their studies. Whether the goal were clinical or laboratory study, the chosen schools were, in a great majority of instances, situated in Germany; the names of Vienna and Paris occurred fairly often, Leyden rarely, Padua hardly ever, if ever. If one turns the pages of Munk's *Roll*, which gives a picture of the educational habits of three centuries of English experience ending rather more than a hundred years ago, we see first the lure of Italy and France and then the attraction of Leyden, which throughout the 18th century attracted a considerable majority of the young British physicians who studied outside these islands. The attractiveness of a foreign school is the resultant of several components, of which accessibility and the reputation of its teachers are the most important. Leyden in the 18th century had both merits; Boerhaave was a great teacher, and after his death his tradition continued. A decreasing resort to foreign universities at the end of the century was due partly to the increasing reputation of our own schools, partly to war, and possibly to the decay of Latin as an international means of communication. When, in the 19th century, foreign study revived, it was purely postgraduate education.

The distinguished historian of medicine, Dr. Max Neuburger, has published a monograph on the Vienna School and its contacts with British medicine which will interest all readers and recall pleasant memories of some senior colleagues.¹ It

¹ *British Medicine and the Vienna School: Contacts and Parallels.* By Max Neuburger, M.D., Ph.D. (Pp. 134; Illustrated. 10s. 6d.) London: William Heinemann, 1943.

is usual to speak of two periods in the history of the Vienna School, approximately a hundred years apart, as golden ages. After the death of Boerhaave, his disciples van Swieten and de Haen were shining lights of the "old" Vienna School. Boerhaave, an enthusiastic admirer of our Sydenham, had immense influence in spreading the Hippocratic methods which Sydenham's clinical genius had quickened; van Swieten and de Haen carried on the good work in the metropolis of 18th-century Germany. It is not likely that many Englishmen studied in the old Vienna School, but Prof. Neuburger illustrates the spiritual affinities of the best British thought with the Viennese teaching. This mutual influence persisted over more than a century.

Of the many hatreds corrupting the soul of Adolf Hitler, a loathing of imperial Austria was not the least. No doubt the principal motive was personal, but it is possible that a dim perception of the good side of old Austria had its part. The Austrian Government often treated vassals with the Teutonic brutality which Hitler might naturally praise, but undoubtedly Vienna was, down to our own day, a civilized capital city, and its intellectual society had an urbanity and respect for the work of other nations which have never been conspicuous in North Germany. The successors of van Swieten and de Haen, in particular Stoll and Johann Peter Frank (whose thought was much influenced by the writings of John Brown), worthily carried on the tradition; and Richard Bright, who visited Vienna in 1814, gave a glowing account of the teaching, mentioning Beer's instruction in ophthalmology, which William Mackenzie described in more detail a few years later.

Prof. Neuburger remarks that one of the most significant achievements of the old Vienna School Auenbrugger's researches on percussion, had small honour in its author's day in Vienna and was brought to the notice of the world by Corvisart and Corvisart's pupil Laennec. After the time of Frank the fame of Vienna waned and Paris attracted a majority of foreign postgraduate students for a generation; accessibility and a succession of brilliant teachers provide a sufficient explanation. But this was not the end. A great clinician, Joseph Skoda, and a great pathological anatomist, Karl Rokitsky, appeared, and the new Vienna School was born. In the early and mid-Victorian period, the zenith of the new Vienna School, the liaison between British and Austrian medicine was close; not only did Rokitsky take great interest in the British literature of pathological anatomy—which, in some points, anticipated his own conclusions—but colleagues such as Hyrtl the anatomist, Brücke the physiologist, and Hebra the dermatologist were well acquainted with English work in their fields. The classical work of Semmelweis—whose treatment by the Vienna faculty did it little honour—attracted much favourable attention in our country. At that time a succession of brilliant ophthalmologists and other specialists were responsible for teaching which earned a reputation assuring a steady flow of foreign students. Indeed, efficiency in special teaching continued to draw students after the general reputation of Vienna as a medical school had been eclipsed by the fame of teachers in North German schools. Felix Semon, who studied in Vienna in 1874, spoke in high terms of the teaching, although he found something to criticize, especially "the want of human feeling shown in the various clinics. In Hebra's skin clinic that indifference occasionally increased to sheer brutality. . . . In Vienna hospitals the patient was merely regarded as 'material.' The poor sick submitted to this with a dull resignation which surprised me at first as much as the want of sympathy of some of their medical attendants."

The primacy of Vienna was over before our younger generation were old enough to be graduates, but the names of Wenckebach and von Pirquet are familiar even to the young. In general one may say that the intellectual sympathy between the English and Viennese Schools was due to a respect for rational empiricism and a distaste for theoretical systems—a Hippocratic rather than Galenic attitude, which the great teachers of both adopted. Vienna is now submerged by a tidal wave of barbarism, but it is not fantastic to expect that the dark waters will recede sooner in Southern than Northern Germany. Vienna has been, what Berlin never was, really cosmopolitan; she may be again.

NEW ZEALAND

[FROM OUR CORRESPONDENT IN WELLINGTON]

Advertising of Medicines

Regulations dealing with advertisements of medicines have been gazetted by the Minister of Health, who explained that they were framed at the request of the board set up under the Medical Advertisements Act passed last year. The board had settled details at a number of preliminary meetings, and would now be in a position to put into operation the provisions which it, as a body of experts, had recommended to the Government.

The main effect of the regulations is to prohibit any claim in medical advertisements (1) to diagnose, prevent, alleviate, treat, or cure a large number of diseases or disorders (including alcoholism, cancer, diabetes, female irregularities, pleurisy, pneumonia, sexual weakness, tuberculosis, and venereal diseases); or to prevent or cure asthma, gout, influenza, obesity, haemorrhoids, or pyorrhoea; (2) that any article or mode of treatment is used or recommended by doctors or other professional men or bodies, with the exception that reference may be made to a named doctor registered in some part of the British Dominions; (3) that any article or mode of treatment is a universal panacea or infallible in its action; or any claim (4) that is false, indecent, or expressed in offensive terms; (5) that, in so far as it relates to therapeutic value, is not based on the advertiser's honest and reasonable belief; and (6) that is intended or likely to mislead or deceive, or to suggest the fear of serious consequences from trivial complaints.

No medical advertisement may invite public correspondence for diagnosis or consultation, nor may it refer to any testimonial for which payment or other consideration has been given. A warning against use without medical advice must appear in every advertisement relating to glandular preparations, and advertisements accompanying preparations containing or purporting to contain a dangerous drug or poison must name the drug or poison and state the proportion present and the maximum adult dose. Recognized pharmaceutical names of drugs must be used in advertisements, and any drug not referred to in standard pharmaceutical works and possessing no recognized botanical name must not be mentioned. Every medical advertisement accompanying any article is to contain specific directions for use.

The board has power to grant exemption from some provisions of the regulations, but not from (1) or from the provisions relating to poisons and dangerous drugs or to the names of drugs. The operative parts of the regulations came into force on Aug. 1, 1943, and in order to give holders time to dispose of made-up packages a further period to Nov. 1, 1943, is allowed in respect of advertisements on or attached to an article or its container. Advertisers who, at the time the regulations came into force, held a stock of advertising material which offends against the provisions relating to the naming of drugs and to preparations containing dangerous drugs or poisons are permitted to continue using it for 12 months thereafter.

The intention of the Act is admirable, and no doubt any defects can be remedied as the result of experience. It does not, however, seem proper to authorize the names of registered doctors in advertisements. Also, the fact that a medicine is approved by a Government board appears to give it official sanction and so greatly enhances the value of the advertisement.

Speaking at the annual meeting of the British Hospitals Association, the Minister of Health (Mr. Ernest Brown) said he had been encouraged by the obvious desire of hospital representatives to work out proposals for an efficient service and by the spirit of give and take which had prevailed. The discussions which had taken place so far had served to make it clear that no onslaught was being planned against the voluntary system; this was a complete misconception. The Government's policy was, and always had been, to make the fullest use of voluntary resources in any post-war hospital service. Changes would be necessary, and if we were to have an integrated and comprehensive hospital service we should have to learn to give up some of our lesser liberties of the past in order to enter into the greater freedom represented by that service. We could not find room in such a service for an independence which was really a disguise for selfish ambition, or a liberty which was really licence.

RADIUM COMMITTEE OF THE KING'S FUND

The Radium Committee of King Edward's Hospital Fund for London, which was first appointed in 1939 and to which there have been references in the last three annual reports of the Fund, has now issued its first general report. The committee has been principally concerned with such matters as wartime precautions in the use of radium, emergency radiotherapy centres, a consultant panel of physicists, organization of radiotherapy in London, and the King's Fund radium pool.

Precautions in the Use of Radium.—One of the committee's first tasks was to see that steps were taken to safeguard radium and to avoid the danger that might be caused to the general public through its dispersal by high explosive. On the outbreak of war, therefore, all the radium was deposited in deep boreholes. Later, however, safeguards were devised which have allowed much of the radium to be withdrawn and put into use. This problem has taken up a great deal of the committee's time, and it has kept in touch with the Radium Commission, which had to deal with the same problem in the Provinces. Following a joint recommendation by these two bodies the Ministry of Home Security issued a pamphlet on the precautions to be taken by all holders of radium.

Emergency Radiotherapy Centres.—The recommendation of the committee and the Radium Commission that special emergency centres should be established for such target areas as London where radiotherapy could be carried on in greater safety was accepted by the Ministry of Health. A scheme was agreed and arrangements made to set up two centres, one of which is now in operation while the other is expected to be ready soon.

Consultant Panel of Physicists.—As a result of the committee's efforts a panel of physicists has been established, which will assist hospitals that have no physicist on their staff and help them to maintain a good standard of technical efficiency. The panel consists of the physicists with the members of their departments from the Medical Research Council and the Middlesex, Royal Cancer, St. Bartholomew's, and Westminster Hospitals.

Organization of Radiotherapy in London.—The committee has expressed its agreement in principle with the views of the Radium Commission on the need for team work in the treatment of cancer and on the requirements of an efficient radiotherapy centre. It has told the Joint Co-ordination Committee that it considers that radiotherapy in London should, subject to the requirements of treatment and teaching, be concentrated at certain of the existing centres attached to general hospitals, and these centres developed by expansion of the staff, equipment, and number of patients served.

King's Fund Radium Pool.—The service of the pool was suspended for some time on the outbreak of war, but it has been gradually resumed. It is still operating on a reduced scale only, and has consequently required less transport.

NEW SALARIES FOR MIDWIVES

In the preamble to the report of the Rushcliffe Committee on Nurses' salaries (*Journal*, Feb. 27, p. 264) stated that a separate committee, with Lord Rushcliffe as chairman, was considering midwives' salaries. The latter committee has now reported,* and its chief recommendation is that State-certified midwives shall be paid according to national salary scales. In making this recommendation the committee has been mindful of the need for making the midwifery service attractive enough so that young midwives will still leave it for nursing. Some of the salaries suggested are as follows:

	Annual Salary	Total Value of Salary and Emoluments
Matron:		
Training institution (50-99 beds)	£275, rising by £25 a year to £400	£425-£550
Assistant matron: 50 beds or over	£230, rising by £10 to £290	£350-£410
Peripartient midwife: Training institution	Range of £240-£340	£360-£460
State-certified midwife and State-registered nurse ..	£150, rising by £10 to £200 (plus £20 after ten years' service in grade)	£250-£320
Midwife: C.M. and S.R.N. ..	£120, rising by £5 to £160	£210-£250

A pupil midwife who is already a State-registered nurse is to receive £65 a year during training (in addition to emoluments worth £5), and a pupil midwife who is not a trained nurse £40 for the first year, £45 for the second, and £60 during the second period

* Cmd. 6460. H.M. Stationery Office. (6d.)

of training. As regards domiciliary midwives, a district midwife who is non-resident and who is also a State-registered nurse is to receive an annual salary of £270, rising by £10 to £360; while a midwife who is not a State-registered nurse will receive £250, rising by £10 to £350.

The committee next recommends that in future midwives should have a uniform, and that the Central Midwives Board should be given power to make rules regarding the uniform, and that it should be an offence for other than State-certified midwives to wear it. It is thought that a uniform will contribute to the public standing of midwives, who bring into the world 400,000 of the 600,000 babies born each year, and act as maternity nurses under doctors' instructions in most of the remaining confinements. The report gives a reminder that midwifery has its own traditions; it is a closed profession, the title of "midwife" being protected by law: unqualified practice being illegal.

Other recommendations are that institutional midwives should work a 96-hour fortnight, have not more than six months' continuous night duty (two months for pupil midwives), free uniform and one day off duty a week. For domiciliary midwives local authorities should establish more district hostels, or in suitable areas provide furnished houses or unfurnished rooms or lodging attendance; they should also provide professional equipment, a stationery, medical supplies, uniform and professional laundry, and should maintain a telephone. All midwives, except pupils, whether institutional or domiciliary, should have 28 days' annual leave with pay. The report also recommended that the practice of charging fees to pupil midwives should be discontinued. Of the shortage of midwives it says the number who complete training would be sufficient to meet demands if they all continued in the service, but the wastage is high. Out of some 65,000 women on the roll only about 16,000 are practising. The wastage has been aggravated by the war because many midwives with the double qualification have turned nursing.

(The Rushcliffe report applies only to England and Wales; recommendations concerning the salaries of midwives in Scotland appeared in the report of the Taylor Committee (*Journal*, Feb. 2, p. 264; and May 29, p. 668).)

PROTECTION FOR THE PRACTITIONER

Sir Robert Hutchison, who presided over the annual meeting of the London and Counties Medical Protection Society in the absence of the president, Sir Cuthbert Wallace, said that every member of the medical profession from the beginning of his career, whatever position he held, should be a member of a defence society. The importance of this was not lessened by the possibility of a State Medical Service. It might be that there were newly qualified men who were neglecting to join such a society in the belief that as servants of the State no action could be taken against them for malpractice. The London and Counties had had to defend its members who were serving in the E.M.S. or in the Forces or were employed by local authorities. If a State Medical Service came into being there was no reason whatever to suppose that a doctor would not still be liable for his actions as a professional man. Sir Robert also said that it would be a great advantage to the society in defending its members if they kept careful records. On many occasions owing to pressure of work, especially in wartime, doctors failed to keep records, and this made the handling of cases on their behalf much more difficult. Another point that constantly cropped up was the importance of a radiograph when there was the least suspicion particularly of fractures. The reasons for not taking a radiograph were understandable and even creditable to the doctor, in that he wished to save his patient expense and fatigue, but it was necessary to have the record. The importance of accurate certification has again been emphasized. Laxity in this respect might involve a member in trouble and the Society in considerable expense.

The Society in its fiftieth year is in a very flourishing condition. Mr. W. M. Mollison, the treasurer, said that during last year recruited a record number of new members (1,349), and the excess of income over expenditure was £6,000, of which £4,000 goes to the accumulated funds and £2,000 to an investment depreciation reserve. The number of applications for advice and assistance from members was nearly one thousand. The officers were re-elected, and votes of thanks were accorded to them and to the staff for their services during the year.

J. A. Dillon and L. R. Evans (*Ann. Intern. Med.*, 1942, 17, 72) illustrate the rarity of primary amyloid disease by the fact that in 120,785 admissions to the Peter Bent Brigham Hospital, Boston, an of 41,551 necropsies there were 23 of amyloid disease, of which only 3 were found to be primary. One of these simulated sclerotic coronary artery disease with heart failure, a second terminated in subacute bacterial endocarditis, and the third showed the symptoms of the nephrotic syndrome.

Correspondence

Health and Social Medicine

SIR.—May I express approval of your leading article on health and social medicine (Aug. 7, p. 174) and, incidentally, in agreement with the letter of Dr. J. Shackleton-Bailey (p. 181) with its pseudo-realistic outlook. It is not the duty of the medical profession to bow to ill-instructed popular clamour any more than it is—as he seems to think it is doing at the moment—to fight for its own privileges. The doctor's duty is to speak and act as he thinks right without fear or favour, and his privileged position has been freely accorded in the past to ensure that his opinion should be free from outside pressure. The Beveridge report seeks to undermine this position in order to transform him into a minion of the State.

The more one considers the Beveridge report and its implications the more one is forced to the conclusion that it is really conceived in plausible ignorance of what doctors can do. As things are they can do relatively little to reduce sickness absence compared with those environmental factors to which your reader alludes and which have been stressed in various letters to the *Times*. Their ability to act like policemen to prevent the abuse of sickness benefit funds is even more limited. For years doctors have tried to do their best, but when I attended a meeting some while ago which discussed, *inter alia*, industrial sickness absence, we had evidence to show that in the case of those firms which continued to pay some of their employees the most reliable and responsible ones, but not of the black-coated class) their wages when off sick, the sickness-absence rate in this class was no less than two and a half times that of the other employees. Considering all the facts one can only come to the conclusion that these employees—who were obviously least likely to malingering—were really the only ones who stayed off long enough to get thoroughly fit. All the others were forced back to work by financial stringency due to the miserable N.H.I. allowance rather than through real physical fitness. This opinion is supported by the way that sickness absence has increased greatly since higher wages have diminished financial stress, in spite of the urgent need for workers to get back to work. The Government actuary, in the Beveridge report, realized that the increased benefits offered might lead to increased sickness claims, and, in the absence of any official figures, he suggested the moderate increase of 12½%. Industrial experience suggests that this figure should have been more like 150% (making a total of 250% compared with pre-war figures). Furthermore, industrial experience does not support the view that financial comfort diminishes sickness absence, nor does medical experience suggest that doctors will be able honestly to diminish it either. For a long time I have realized that many of my N.H.I. patients were going back to work before they were medically fit, and as a doctor I should rejoice to see the length of sickness absence increase for many of them.

If this is true, and I think it is, both the finances and Assumption B of the Beveridge scheme are seen to need very considerable revision, for Assumption B is asking of the medical profession something that it is quite powerless to give without losing its status of being composed of honest physicians instead of time-servers. We may offer a "flea-bite" to offset the 250%, but that is all. A disturbing thing about the Beveridge report is that it can only function in a world at peace, and yet, for the preservation of that peace, we seem destined for many years to have to exercise, as a nation, just those qualities which the Beveridge report tends to lull to sleep in the individual. This paradox may be resolvable, but at least it should be squarely faced. Personally I find very little enthusiasm for Beveridge among my patients. Many of them realize subconsciously what the report says of itself, that it is an attempt at revolution—"A revolutionary moment in the world's history is the time for revolutions, not for patching" (para. 7). Many of us think that wartime is about the unwise time of all to attempt a revolution of such social complexity and significance, especially when those most likely to be affected are unable to take any part in enacting it. If the doctors can call a halt until the matter has been more

fully considered in all its implications we shall have justified our existence as custodians of sanity as well as of health.

There is another passage in the Beveridge report, in paragraph 440, which is never quoted, although it is perhaps the most important of all. It says: "Fourth and most important, income security, which is all that can be given by social insurance, is so inadequate a provision for human happiness that to put it forward by itself as a sole or principal measure of reconstruction hardly seems worth doing." The key to happiness and healthy living is not more doctors, or regimentation of or by the doctors or the State, but in developing a healthy community spirit and paying attention to those physical, environmental, social, and spiritual factors which promote health or predispose to disease.

I should perhaps add that I am heart and soul in favour of social advancement. But a scheme which has been put before the public so much as "get" instead of "give," emphasizing rights rather than duties, is bound in the long run to lower the temper of our living and increase selfishness and therefore misery. There must be a community before rights can be exercised, so social obligations must be admitted before social rights can be claimed. This is not overlooked in the report, but it has been obscured by the blaze of publicity with which it has been accompanied.—I am, etc.,

W. N. LEAK.

Responsibility and Freedom

SIR.—I must admit that one of the reasons for my claiming a few lines of your space is that I do really believe we are in danger of losing what the letters to the *Journal* most especially symbolize—the free expression of individual opinions. If we are all to be State paid we shall not be able to publish our critical feelings, except, perhaps, in the form of scientific papers, and scientific psychology is not yet able to provide a vehicle for every shade of feeling. The actual thing which I wish to say concerns one aspect of the State medicine controversy. State medicine and personal medicine have interests which only overlap; they are not identical, and in regard to extremes they are actually *opposed* to one another. Are this and its significance fully recognized?

Take vaccination. The State obviously needs the maximum control of small-pox. We, as individuals, expect the State to take over this matter, and in an epidemic we blame the State medical service. But even in this obvious case there is also a personal problem, and many a doctor who has advocated compulsory vaccination has found it difficult to have his own baby vaccinated. If he has happened to witness one of the rare complications of vaccination he may easily have felt that a good case might be made out for postponing vaccination in the exceptional case of his own baby. How much more does the uninformed member of the public need to be personally represented against the State. Only if his own doctor, who has helped him fight battles before, advises in favour of vaccination is he led to agree to have it done. The fact that the State advocates it is scarcely an argument at all, since it is obvious that the State cannot take much account of individual needs. If it did it would fail to control small-pox. This meagre example must suffice to illustrate the contrast that exists between the aims of State medicine and personal medicine.

In this matter the public should be actively educated by us before they vote away our power to be their personal doctors, since we are the ones who know most about their own need of both personal and State medicine. And we should also tell the existing State service how it needs the services of a personal doctor, by which, in this context, I mean the clinician whose aim contrasts with the aim of the State doctor. The support of the individual members of the public has to be continually won for the actual practical details of State medical practice. And it is the personal doctor who is continually persuading sceptical people (who have learnt to trust his judgment) to undergo inoculations, immunizations, operations, and all sorts of treatments whose value seems entirely obvious to a non-clinical Ministry official. And the reason for the clinician's power to help the State in this way is that his aim is not primarily to serve the State, but is to serve the State secondarily through giving the best possible service to the individual.

One of the best guides to the personal doctor is his willingness to take personal responsibility for cases. No Ministry official ever takes personal responsibility for individual cases, and this makes him an absolutely different being from the clinician. His week-end or his holiday do not mean an increase in the risk that this patient will commit suicide or that one will relapse into a new active phase of rheumatoid arthritis or anorexia nervosa. His work is of a different order and can scarcely be compared with that of the G.P.

In fact, the two have the greatest difficulty in understanding one another, the G.P. looking on the Ministry official's job as a sort of rest cure, and the official looking on general practice as if it were comparable to going to an interesting play or film. In truth the G.P. would be utterly bored by the official's job, and the administrative official would be overwhelmed and even frightened to find himself in general practice. Obviously the two jobs are two jobs. It would always be important, in discussions of the current problems, if each speaker would indicate whether he in his work does or does not take responsibility for individual cases.

All this leads up to my main point, which is, that if all doctors are forced to adopt the State service, then the personal clinical work will immediately be taken over by the unqualified practitioners, to the immense harm of the public. Osteopaths and all kinds of quacks will make a lot of hay in this their new sunshine, and the bad thing is that they will be actually more valuable to the individual members of the public than the doctors. This hay-making will only end when the public demand the inclusion of the quacks in the State medical service. (Clamour for the inclusion of osteopaths has already started.)

Some doctors have naively said that with total State medical services non-medical practice will be more successfully controlled than it is at present, but State medicine is the servant of Parliament, and I have no doubt that an election fought on this subject would return a majority against the exclusion of the unqualified practitioners. Unqualified practice is very widespread, and it will increase as medical practice becomes more scientific, psychological practice being entirely unable to cope with the enormous mass of hypochondria which doctors are becoming too well informed and too honest to treat by other than psychological means.

The upshot of all this is that there is as much need for personal medical practice as there is for State medical practice, and that the two can never become identical, because in certain circumstances their aims are opposed, however much in other circumstances they overlap. Also, the right of the individual to go to an unqualified practitioner should be stoutly upheld by the medical profession, at least until all hypochondria can in practice be treated along scientific lines, and we are at least a century away from such a novel state of affairs. Let us allow our hypochondriacal patients to escape from us to the local osteopath, and there to lose their symptoms which we could not shift (having no access to magic), and at the same time let us die rather than admit any unqualified practitioner into our beloved profession, which eschews magic and at least tries to be scientific. Our new-growing knowledge of the psychology of hypochondria is the only promise we have of a future in which we can offer the public cure of common symptoms without going off the track of scientifically constructed theory. Total State medicine will most endanger us by forcing the issue on this matter of common hypochondria before we are ready for it, and by tempting the public to exercise its new power over us by forcing into our ranks the unscientific symptom-removers, the unqualified practitioners.

I am sorry that this letter is so very long, but it is impossible to state these matters, which are very much more complex than I have represented them to be, intelligibly in a word.—I am, etc.,

London, W.1.

D. W. WINNICOTT.

Report of Representative Committee

SIR,—This report should receive our common appreciation and warmest support. I venture to suggest three points of importance in the "General Principles" (Supplement, Aug. 7, p. 19) calling for amendment.

1. Surely "the health of the people depends primarily" on their will as well as their opportunity to help themselves. There is far too much talk of what the community must do for the individual as compared with what the individual can and should do for himself. The words "and upon the will of the people to help themselves" should be added.

2. Is "the central administration . . . concerned only with civilian health services" to be a Ministry of Health stripped of its responsibility for local government and housing? If so, local authorities will look to other Departments for guidance, and health will again become the "Cinderella" of local government. Why not call this central administration the "Ministry of Health" and strengthen it as suggested in the report?

3. "Locally, new administrative bodies . . . should be representative, . . . in appropriate numbers, of the local medical profession." Are these bodies to supplant the county and county borough councils and the local sanitary authorities? If so, they must be elected by public vote and will not be representative of the local medical profession. If not, they will not have the power of the local authority, its officers, and

its purse; they will be yet another extra body to complicate and delay matters. Local government cannot be split between health matters and others. The expected reform of local government will, it is hoped, provide bodies, elected by the people and directly responsible to them, who will be more and more influenced by the other "local medical advisory committees," rightly proposed in this report.

The more medical men in local, as in national, government the better. But do not let us tinker with the democratic system, however faulty, of elective governments, local or national, giving the people the doctoring they want, in favour of a corporative exception, redolent of Mussolini.—I am,

Hatfield.

FRANCIS FREMANTLE

Oestrogens at the Menopause

SIR,—The author of the answer to the question under title in the *Journal* of Aug. 7 (p. 190) rightly warns against "prolonged and heavy dosage." In discussing the details of dosage, however, he advocates beginning with 0.5 mg. two or three times daily by mouth of a synthetic oestrogen such as stilboestrol or hexoestrol; increasing cautiously until a dose is found which will give relief; maintaining this dose for two or three weeks; and then reducing it gradually over 3 to 6 months. Thus the patient would receive more than 1 mg. every day for anything from 4 months to a year. In my experience such dosage is quite unnecessarily high, and, in my opinion, so prolonged and heavy dosage is most undesirable.

I have on numerous occasions obtained satisfactory subjective improvement, using the hot-flush counts as an indication and in some cases oestrogenic changes in the character of "menopausal" vaginal smear, on doses of 0.1 to 0.5 mg. natural oestrogens by mouth (and stilboestrol is two and half times as effective by this route as the natural oestrogen). Indeed, a fairly extensive experience of oestrogenic therapy spread over the past 10 years has led me to suspect that symptoms in women of menopausal age which do not respond to less than 1 mg.—other than such late sequelae as atrophic vaginitis—are not due to ovarian deficiency. Women vary considerably during the different phases of their life span in their sensitivity to oestrogens. For instance, during pregnancy and the puerperium they can tolerate quite fantastic doses. Abarbanel and Klein¹ gave as much as 500 mg. of stilboestrol daily for 4 days to mothers suckling infants. On the other hand, the menopausal woman is relatively sensitive to oestrogens.

Overdosage may be accompanied by such undesirable immediate effects as profuse uterine haemorrhage, swelling and tenderness of the breasts, headaches, minimal feelings of fullness, and peripheral vasodilatation. Furthermore, if synthetic oestrogens like stilboestrol are employed such toxic by-effects as anorexia, indigestion, nausea, and vomiting are not only more likely to be manifest if high doses (i.e., 1 mg. or more) are given but are much more prone to develop in the menopausal age than in younger women, or during pregnancy and the puerperium, when such symptoms never follow even very high doses. But these are only minor inconveniences which label the treatment at best inartistic. The are three other aspects of high dosage, however, which are more important.

It has been shown (Bishop and McKeown²) that high doses of oestrogen renders the organism immediately less sensitive to subsequent dosage, so that it will no longer respond to what was previously a minimal effective dose. Thus the process of "weaning" will be considerably prolonged. Secondly, it has been shown that continued high dosage may give rise to pathological changes in the endometrium characterized by cystic glandular hyperplasia with troublesome and persistent uterine haemorrhage. Nor is the prolonged inhibition of pituitary activity which results from continued high doses of oestrogen to be lightly discounted. Finally, the carcinogenic tendencies of oestrogens have been fully considered in the light of animal experiments, and though it seems clear that provided oestrogenic therapy is applied in interrupted courses it is quite harmless, the daily administration of doses of over 1 mg. for prolonged periods in cancer-susceptible strains (e.g., in women with a history of carcinoma of the breast) may not be without

¹ *New York St. J. Med.*, 1941, 382.
² *J. Endocrinol.*, 1940, 2, 339.

sk. I believe, therefore, that the promiscuous use of oestrogens in doses of 1 mg. or more is highly undesirable and may actually be dangerous.

The author of the answer to the question on oestrogens at the menopause states that oestrogenic therapy is indicated in only 20% of menopausal women. My experience, which coincides with that of Hawkins,* who reported on 1,000 menopausal women, is that about 75% of menopausal women require oestrogenic therapy, and that provided it is given in low dosage and with intervals of remission of treatment the results are most satisfactory and that undesirable by-effects seldom supervene and are of little account.—I am, etc.,

Endocrine Clinic, Guy's Hospital, S.E.1.

Specific Gravity of Cerebrospinal Fluid

SIR.—In his article (Aug. 7, p. 165) Mr. W. Etherington-Wilson asserts that all previous observers have been wrong and that the average specific gravity is nearer 1.003 than 1.004. He bases this statement upon observations made with beads in 314 specimens of fluid at body temperature.

May I point out that density beads are made to work in a medium at 15° C., at which temperature distilled water is given an arbitrary figure of 1.000. At any other temperature the necessary correction must be made. For example, at body temperature (37° C.) the figure for water or standard of comparison is 0.996, which would bring the true specific gravity up to the accepted average figure of 1.007. If Mr. Etherington-Wilson will continue his investigations, using the direct method of comparing the weights of exactly equal volumes of cerebrospinal fluid and freshly redistilled water under the same conditions of temperature, etc., I think he will find it unnecessary to modify our textbooks on physiology.

The classical work on the subject by Levinson tabulates the figures arrived at by 13 different observers. These agree closely, and it can be taken that in health the specific gravity varies between 1.004 and 1.010. In uraemia and diabetes the figure may exceed 1.010, while in hydrocephalus it may be below 1.004. J. K. Hasler has pointed out that fluid obtained by cisternal puncture is slightly lighter, as it contains less protein.

Finally, I might point out that the figure of "nearer 1.003 than 1.004" could not be accurate, as in this case "lighter" would be either isobaric or slightly hyperbaric. In his event the technique which Mr. Etherington-Wilson himself uses would be impossible.—I am, etc.,

St. Albans.

C. LANGTON HEWER.

The Mastoid and D. and V.

SIR.—The literature of infantile otogenic intestinal troubles has received a contribution from Mr. P. W. Leathart (Aug. 7, p. 168). This literature has at times leaned towards mere paracentesis, at other times towards more major surgery. In one decade the label has been latent mastoiditis, in another cryptic; now it is plain unvarnished mastoiditis. While truth no doubt is absolute, Mr. Leathart essays proof, and herein there is doubt.

Nothing in the evidence forces me to any such conclusion as is distilled rather prematurely in the closing sentence of paragraph two. The argument as it relates to the infantile Eustachian tube may be worthy of attention, but it is distressing to find that the infant is to be condemned to a double mastoidectomy because a posterior triangle gland can be rolled under my fingers.

As a concession to tradition we are told that "it would appear relevant to state that the remarks made above are the result of work done chiefly at the Royal Liverpool Children's Hospital in co-operation with the physicians and surgeons during the last 20 years." I feel, however, that before other surgeons are encouraged to operate on 2,000 infantile mastoids we may be vouchsafed a further concession. It is this: we should have something more than the bald statement that "without surgical aid all [presumably 2,000 cases] would have died." It may be true, but the evidence on a question so very serious is of the scantiest.—I am, etc.,

Newcastle-upon-Tyne.

F. MCGUCKIN.

Peripheral Arterial Embolism

SIR.—The article by Major H. Agar (July 24, p. 101) on peripheral arterial embolism leads me to record the following case, underlining as it does Major Agar's statement that "many cases [of embolic occlusion] are missed."

A woman aged 54, who had suffered from auricular fibrillation for many years, was admitted to the Manchester Royal Infirmary at about 7 p.m. on Dec. 29, 1942, with a history that she had been seized with severe pain and paralysis of the right leg five hours before. She was examined by a newly qualified house officer, who had unfortunately not seen such a case before. He diagnosed femoral (venous) thrombosis, and admitted the patient to a medical ward. She was seen at about 12.30 a.m. that night by the resident medical officer, Dr. O. Janus, in the course of a routine round, who at once made the correct diagnosis of common femoral (arterial) embolism, and got in touch with me. I performed an embolectomy within the next hour, but although the profunda femoris artery could be cleared of clot, the superficial femoral was completely full and also in spasm. The tunica adventitia was stripped around the bifurcation of the common femoral and the incision then closed. Within the next few days the patient went into a state of anuria, reminiscent of that occurring in crush syndrome, but this settled down. Meanwhile the lower part of the leg had developed a moist gangrene, the line of demarcation being just below the knee-joint. On Jan. 28 amputation was performed through the junction of the middle and lower thirds of the thigh under spinal anaesthesia, but 24 hours later the patient suddenly collapsed and died. A post-mortem examination was not permitted.

The point which I wish to emphasize is that, although I agree with Major Agar that the diagnosis of peripheral arterial embolism is usually easy, it might be better to say that the diagnosis is usually easy for anyone who has seen a case before. I would suggest that it would be a good guiding rule if students were taught that whenever a sudden paralysis or a sudden vascular upset of a limb occurs the case should be regarded as one of arterial embolism until proved otherwise (e.g., by the presence of pulsation in the peripheral arteries, etc.). As things are at present, I have the feeling that the work of Griffiths and Jefferson performed in this hospital on peripheral embolism is being largely wasted, because the frequency of the condition (at least eight cases have been admitted to the Manchester Royal Infirmary in the last 18 months, most of them long after the time for embolectomy) as well as its extreme urgency is insufficiently realized.

Despite the failure of embolectomy after 11½ hours in this case I fully agree with Major Agar that operation within the first 12 hours at least is always worth while if there is any chance of the patient surviving it.—I am, etc.,

A. N. GUTHKELCH,
Resident Surgical Officer.

Manchester Royal Infirmary.

Rupture of Rectus Abdominis during Pregnancy

SIR.—On reading the interesting article by Mr. Rufus Thomas under this heading (July 31, p. 136) I was reminded of a similar case which occurred in this hospital last year.

The patient was a 4-para aged 34; she was admitted as an emergency on May 16, 1942, with a diagnosis of ruptured uterus. On admission she gave a history of having fallen flat on her abdomen ten days previously while moving some furniture. Ever since there had been pain and tenderness on the left side of the abdomen. She was a chronic bronchitic and very obese. She was not collapsed or shocked: temperature was 98°, pulse 92, and respiration 20.

The uterus was enlarged to the size of full-term pregnancy and the presentation was made out with difficulty to be a vertex. The foetal heart was audible and there was no vaginal bleeding. The uterus appeared very tender and swollen on the left side. The urine was clear and the blood pressure 122/78. A provisional diagnosis of concealed accidental haemorrhage was made and the membranes were punctured artificially. The liquor was clear. There was a latent interval of five days before pains started, and during this time the patient's general condition improved considerably and the swelling became, if anything, less painful. The patient's cough also improved.

She had a normal confinement on May 22 lasting 6 hours 10 minutes; there was a moderate post-partum haemorrhage, which responded to the usual treatment. The child was alive and weighed 6 lb. On examination after the third stage a large rounded mass was palpable extending above and to the left of the umbilicus. This was thought to be an ovarian cyst, and as there was no definite evidence of torsion it was decided to leave well alone. The first

two days of the puerperium were satisfactory, but on the third day there were acute abdominal pain and pyrexia, temperature 101°, pulse 116. A laparotomy was therefore performed, as it was thought that the cyst had twisted. The uterus and adnexa, however, were found to be perfectly normal. The large swelling was in the rectus sheath, and several huge clots and about 3/4 pint of old fluid blood were evacuated from the left rectus sheath. The wound was sutured and a large drainage tube left in the haematoma cavity. The patient made a good recovery and was discharged from hospital on June 20.

The great difficulty in this case was the gross obesity of the patient, which led to a false feeling of encapsulation of the haematoma, making it appear an intra-abdominal mass.—I am, etc.,

Newport, Mon.

NORA L. KEEVIL, M.D., M.R.C.O.G.

Sterile Solutions and Vaccines

SIR.—Perhaps this idea may help those practitioners who have been at pains to keep sterile any rubber-capped bottles of vaccines and other solutions for injection. The main difficulty appears to be the preventing of ingress of unsterilized air, and yet removing the negative pressure which must result from repeated withdrawals of measured portions of fluid. I suggest the following procedure:

1. Sterilize, by boiling, a small fine-bore hypodermic needle. Dry by running through spirit ether.

2. With sterile forceps pack the hollow of the head of the needle with sterile dry cotton-wool.

3. Pierce the rubber cap of the bottle at one side with the needle and leave *in situ*.

Air can now enter the sterile inside of the bottle, but organisms are filtered off by the tight plug of cotton-wool.

This procedure should be quite effective in keeping the contents of the bottle sterile and yet allowing air to enter. The safeguard is the same as used by Pasteur in his flask experiment and by bacteriologists in the use of culture-tubes. Withdrawals of fluid can be made as usual from the central portion of the cap.—I am, etc.,

Aston, Birmingham.

C. COLEY GRAYSON.

Fracture-dislocation of the Spine

SIR.—It was with very great interest that I read the report of the recent meeting of the British Orthopaedic Association and your summary of the papers given by Mr. R. C. Murray and Mr. Roland Barnes (July 24, p. 114). It is to be regretted that the report of these two papers could not have been given in greater detail.

More than five years ago I called attention to interlocking of the articular facets as a frequently occurring complication of fracture-dislocation of the spine and, with the encouragement of my then chief, Mr. C. Gordon Irwin, described three cases treated by open facetectomy (*Brit. J. Surg.*, Jan., 1938). Subsequently experience of some fifty cases of fracture-dislocation of the lumbo-dorsal spine, with and without cord or cauda equina lesions, more than thirty of which number I have personally operated upon, leads me to offer the following comments which, I trust, may be of interest.

1. Mr. Barnes states that locking of the intact articular facets occurs more commonly than is generally realized. I would go much further than that and state that fracture-dislocation with transposition of the articular processes is the commonest form in which the injury occurs; more than 50% of my cases have been of this type, either bilateral or unilateral. Consideration of the component parts of the intervertebral articulations will show that for intervertebral displacement to occur the articular processes must dislocate or must be broken off. Cases showing dislocation on one side and fracture of the processes on the other are not uncommon. Only two cases in my series showed fracture of the processes on both sides and direct forward displacement of the upper vertebra; such a condition, one assumes, would tend to produce a scissoring of the spinal contents, and the prospect of recovery would, in consequence, be nil—this was true of one case. The second case showed an incomplete cord lesion on admission; reduction was attempted as soon as possible, open operation being required to remove fragments of the processes which were preventing reduction. During the next three days the nervous symptoms progressed to

complete paraplegia below the level of the umbilicus. This state of affairs persisted for three weeks, after which time a gradual recovery began, and when I last saw this patient he had regained bladder control and was being taught to walk.

2. In view of the above successful case and of others which have shown varying degrees of recovery, Mr. Murray's limit of 24 hours for recovery from a complete paraplegia seems rather pessimistic. My impression is that signs of recovery should be present within three days of operation if full recovery is to be expected. Signs of recovery after three days give promise of a greater or less degree of ultimate recovery, depending upon the time lapse between operation and the first appearance of returning function. After three weeks any further recovery can be limited only to roots release from tension at operation. In this connexion I entirely agree with Mr. Murray that reduction should be secured in all cases, since the recovery of a few useful segments can be expected in almost all this may make the difference between a bedridden patient and one who at least can make some effort to help himself.

3. In my own series of cases dislocations located in the dorsal 12 region have included an almost equal number of paraplegic cases and cases in which nervous signs were either entirely absent or were limited to temporary root palsies. I have recently operated upon three cases of the latter type and all are now back at work. Two similar cases, operated upon during 1938 and 1939, are also back at work, one of them actually undertaking work of a heavier nature than that upon which he was employed before his accident.

4. Unskilled attempts at reduction, or hyperextension of the spine as a first-aid measure, are to be strongly deprecated. When the articular facets are transposed intact hyperextension of the spine produces further strain upon the already attenuated spinal contents and may cause irrecoverable damage. Reduction should be undertaken only by a surgeon in possession of adequate x-ray evidence of the spinal displacement. Patients should not be hyperextended as a first-aid measure but should be transported to hospital "as they are." If a "hyperextension stretcher" is used the patient should be carried in the prone position.

5. The actual operative procedure will depend upon the anatomical deformity revealed by x rays. Not all cases will require open operation. Subluxations, or unilateral dislocations such as described by Wilfrid Adams, if they occur below the ribs can sometimes be reduced by rotary manipulation; such manipulation should be carried out under local anaesthesia, since general anaesthesia removes the only means of checking the safety of any manipulative manoeuvre. It has occurred that a case of fracture-dislocation without nervous signs has been manipulated under general anaesthesia and the patient has awakened to the presence of a paraplegia, the dislocation being still present and requiring open operation for its correction (Rogers, *J. Bone Jt. Surg.*, 1938).

I agree with Mr. Barnes that excision of the whole of the superior articular process is to be avoided wherever possible. It is preferable, however, to resort to removal of the tips of the processes rather than to the use of levers. Removal of the tips of the processes does not materially weaken the spine—as my own cases have proved to my satisfaction—and additional internal fixation in these circumstances would appear to be unnecessary. Only one case in my series required laminectomy, and that only because the lamina had been fractured and displaced so that it interfered with reduction. For fixation after reduction, as a routine I now apply a full hyper-extension plaster jacket, this being more rapidly prepared than a plaster bed, and cut a trap-door in the plaster over the region of the wound. Non-paralytic cases retain the jacket until ready for walking (about three weeks); it is then changed and the new jacket is retained for four to six months. In paraplegic cases the jacket can be bivalved, if necessary, at any time. The nursing staff assure me that nursing attention is usually easier when the jacket is intact. In paraplegic cases the limbs are raised and slung up on Braun's splints to avoid gravitational oedema and to relieve some of the pressure upon the sacral area.

6. The best treatment for the paralysed bladder is a careful house-surgeon. All methods appear to have their disadvantages. I favour the use of the catheter and daily wash-out during the first week or two, in anticipation of the return of bladder control or of the establishment of reflex evacuation, after three weeks' tidal drainage and, later, suprapubic cystostomy for those cases which fail to regain either voluntary control or reflex emptying.

In my original publication I expressed the opinion that open operative reduction appeared to be a rational method of treatment and one likely to produce the maximum benefit at minimal risk. I also expressed the hope, since none of the original three cases was fully cured, that others might feel disposed to employ this method in similar cases. It is very encouraging to note from my own experience and now from that of others that fracture-dislocation of the spine is no longer a condition beyond the effective aid of surgery.—I am, etc.,

Durham.

A. H. G. MUNRO.

The Government's Milk Policy

SIR.—It is more than disappointing to find that in the White Paper on measures to improve the quality of the nation's milk supply the Government has only dabbled with the problem. While no one disagrees that "the basis of a sound policy . . . is a well-bred, healthy herd," it is a far cry from that to a milk supply safe to give our children. To admit, in effect, that in England and Wales only 6% of the milk is "not satisfactory" is more than a confession of weakness. We shall not be in a position to prevent milk-borne infection until all milk is pasteurized efficiently and all milk reaching and saving the plants is of the highest standard. The production of well-bred healthy herds is an ideal to be aimed at none the less if milk is to be pasteurized, but pasteurization is the only immediate means of securing a safe milk supply.

Once again it must be reiterated to the public, if not to the profession, that pasteurization has one practical effect and one only—namely, to render the milk germ-free. T.T. milk will not be free from abortus infection, streptococci, diphtheria, typhoid, dysentery bacilli, etc., and veterinary examination of the herds will not detect the milk with a throat infection contaminating the milk. If farmers have to be exhorted in the daily press to take such an elementary precaution against infection as to wash their hands before milking each cow, it is unlikely that they will be easily trained in the art of producing a germ-free milk. An American Army medical officer in this country was so disgusted with what he called our "street-can methods" of handling milk that he has issued an order forbidding any of his troops to drink British milk!

When doctors, especially those dealing with children, see every day some evidence of milk-borne disease, it is natural that they should demand from the Government not "measures to improve the quality of the milk" but measures to render milk safe to drink, and be critical of its half-hearted method of appeasement to the farmers—a policy in which one hoped it had learnt its lesson.—I am, etc.,

Cardiff.

A. G. WATKINS.

X Rays and the Colon

SIR.—Referring to the statement in the *Journal* (July 10, p. 51) that Sir Arthur Hurst "warned strongly against x-ray examination as a method of diagnosis" for diseases of the colon, and the subsequent valuable comments by Dr. E. Millington (July 24, p. 117), may I, as radiologist in charge of the x-ray department of St. Mark's Hospital for Bowel Disease, E.C.1 (a hospital known throughout the world for its contributions to this specialty), submit a few observations in the hope of retrieving Sir Arthur Hurst's lost faith in the opaque enema. As I have not carried out any radiological examinations for Sir Arthur I cannot be implicated personally.
